Such being the position of things, I would venture to draw attention to the following plan of treatment, which, in the two cases in which I have as yet tried it, may be considered to have met with a degree of success. On examining these ulcers it is obvious that the dense rigid ring of heaped-up epithelium that surrounds the sore or sinus forms a very grave bar to healing. The ulcer could never heal so long as its margin is set in an annular induration that prevents an approximation of its edges and an opportunity for the display of the healing process. Even if the ulcer were to become filled up with granulations its final closure would still be a matter of considerable difficulty, since the skin, that takes so active a share in the healing of such lesions, would be seriously hampered in its activity. The plan alluded to is this: The patient is confined to bed and the sole of the foot is kept continuously poulticed with linseed meal. This causes the epithelium to soften and swell up, so that at the end of twenty-four hours the ring around the sore appears as a very prominent softish white mound. All this redundant epidermis is then shaved away with a scalpel, and the poultice is reapplied. At the end of another twenty-four hours the deeper layers of epithelium that were not affected by the first poulticing have become swollen and prominent. They are in turn cut away. The poultice is again applied and the scalpel used day by day, until the whole of the epidermic mass has been removed. This object will be effected at the end of about ten or fourteen days. By this time the skin about the ulcer will, as a result of the continued poulticing, have peeled off in a thick white layer, and around the sore will be nothing but thin fresh pink epidermis, looking active and healthy. The ulcer in the meantime will be found to have cleaned, and by the loss of its cutaneous boundary will appear less deep. The poultices are now discontinued, and to the sore is applied a paste, of the consistence of thick cream, composed of salicylic acid and glycerine, to which is added some carbolic acid in the proportion of ten minims to the ounce. This paste is applied on lint, and is quite painless. The ulcer soon heals, and when the patient gets up he is instructed to wear a thick pad of felt plaster over the spot, with a hole in its centre that corresponds to the scar of the recent sore. This plaster should be always worn. As one objection to this measure it may be urged that, although pressure may be taken off one part of the sole, an ulcer may appear at some other spot where pressure has effect. So far as my two cases go, this result has not yet happened; and it is to be noted that, although a large area of the sole is normally exposed to pressure, these ulcers have a tendency to appear only in certain spots. The patients should also be instructed to pay great attention to the cleanliness of the feet, to wear well-fitting woollen stockings and easy boots.

CASE 1.—A man, aged thirty-seven, was admitted into the London Hospital under my care on May 9th, 1884. He had a perforating ulcer of the sole of the usual appearance, over the metatarso-phalangeal joint of the third toe of the right foot. The ulcer extended down to the bone, which was, however, not bare. He had been under the care of my colleague, Dr. Ralfe, for locomotor ataxy. He suffered much from lightning pains in both legs, and there was an absence of patellar reflex on both sides. The ulcer has existed for three years, and has resisted all treatment. He is a cigar maker by trade, but as his employment requires

[1] Vol. lviii., p. 384.

Digitized by Google

much standing he had not been able to follow it regularly owing to the pain caused by the ulcer. The treatment by poulticing was commenced on May 12th. By May 28th all the thickened epidermis had been removed, and the salicylic acid paste was applied. On June 11th the patient was discharged with the ulcer entirely healed, and with a disc of felt plaster applied to the part.—Oct. 10th: The patient has regularly followed his employment since his discharge. The ulcer shows no relapse, and there is no indication of corn or ulcer on any other part of the sole. At one time since his discharge the patient left off the felt plaster, but the site of the ulcer became sore, and he was obliged to take to the felt again. The foot is now entirely free from pain, with the exception of the occasional lightning pains above referred to. In this instance an ulcer that had lasted for three years was cured in four weeks.

CASE 2. — The patient is a gasfitter, aged thirty-eight. He was admitted on Aug. 12th, 1884. He had a perforating ulcer of the usual kind on the plantar aspect of the left great toe. It extended down to the bone, which was, however, not bare. The toe was much swollen. There was grating in the metatarso-phalangeal joint. The sore had existed for four years. Eighteen months after its first appearance it had healed under treatment. It soon, however, broke out again, and has existed as a deep discharging ulcer ever since. The patient suffers from lightning pains, and the patellar reflex is entirely absent on both sides. His gait is normal, but he is unable to maintain his equilibrium when his eyes are closed. He is troubled with some incontinence of urine. His pupils are much contracted. They respond to accommodation, but not to light. The treatment was commenced on Aug. 12th. On the 19th the poultices were discontinued and the paste applied. The man was discharged on the 30th with the ulcer entirely healed.—Nov. 15th: The patient has followed an active employment as a gasfitter since his discharge. He has always worn a felt plaster over the site of the ulcer. The ulcer is entirely healed, and the foot has given him no trouble since he left the hospital. Previously to his admission the pain caused by the ulcer had often seriously interfered with his employment. In both this and the previous case there was apparently no loss of sensation in the integuments of the sole. In this instance a sore that had existed, with the exception of one short interval, for four years yielded to treatment at the end of eighteen days.

NOTE ON THE OPERATION OF TRACHEOTOMY IN CASES OF DIPHTHERIA OR CROUP.

BY JOHN W. OGLE, M.D., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL.

IN consequence of the recent and lamentable death of Dr. Rabbeth various contrivances have been recommended as substitutes for the oral suction, which is, at times, and at a moment's notice, necessitated when opening of the larynx or trachea has been resorted to, in diphtheria or croup. I would suggest that such suction would be rendered free from any risk provided that a piece of some very thin, soft, and pliable material, such as extremely delicate cambric or silk (or so-called "grenadine" or "gossamer"[1]), three or four inches square, were laid over the windpipe and so adapted as to form a small pouch or sac over the orifice made therein, which should be received into the mouth of the operator before the suction was practised. The character of the tissue or material would permit of the movements of the lips and tongue, appropriate to the act of sucking; and the diphtheritic stuff would be almost as easily drawn into the sac contained in the mouth as if nothing had been interposed between the windpipe-orifice and the cavity of the operator's mouth. It would doubtless be, also, advantageous if the substance forming the sac or pouch into which the diphtheritic material would be sucked were well moistened by some suitable antiseptic liquid, such as a solution of boracic or salicylic acid, or a spirituous solution of thymol or diluted oil of eucalyptus. By such a procedure as the above described the diphtheritic films and fluids aspired into the mouth would not, in any case, come into direct contact with its lining membrane; and in this way danger to the operator would be entirely obviated.

It has been thought that most likely the evil (and occasionally fatal) results which have occurred to operators after sucking deposits into the mouth have been consequent on some abrasion of the mucous surface. It is, indeed, generally conceded that diphtheria cannot be communicated to any part of the *skin* unless there be some lesion of continuity of the surface; but the details of such remarkable cases as Trousseau[2] and others relate, in which physicians have contracted diphtheria from patients and succumbed to the disease, seem to show, unequivocally, that the entirety of the surface of the mucous membranes does not by any means confer an immunity from contagion. The diphtheritic membrane in the mouth and throat has, from time to time, been dissolved by escharotics, astringents, &c.; and it has been suggested that possibly local agents might be of service in diphtheritic and other false membranes lining the windpipe, but of course the difficulty consists in applying them. If their application were practicable, and there were sufficient time for their action, most likely substances which possess a solvent power over albumen and fibrin, such as acidulated pepsine and lactic acid, would be those selected for the purpose alluded to.

Before closing this note I wish to mention that Dr. Ewart, of St. George's Hospital, has observed to me that probably in cases where diphtheritic and other morbid products have to be sucked into the mouth, the operator, by rinsing out the mouth previously to the process of sucking, would be able to shield the mucous surface from contagion.

A NEW NEEDLE-HOLDER.

BY J. WARD COUSINS, M.D. LOND., F.R.C.S.,
SURGEON TO THE ROYAL PORTSMOUTH HOSPITAL.

THE special feature of the instrument consists in the novel device by which the opening, shutting, and fixing movements are accomplished. The blades are surrounded by a triangular collar with rounded angles, fixed just below their points, and under the control of the thumb by means of a lever. When the holder is grasped by the hand, this collar can be easily rotated. In its long axis the blades are released by a recoil spring, but by a slight movement they are securely fixed, and the points are brought into close contact with each other. The holder is represented in the engraving carrying a surgical needle and thread. It is adapted for the introduction of every kind of needle, and it is not liable to get out of order. The pressure at the points can be accurately regulated by the hand of the surgeon, and thus the risk of breaking needles is greatly diminished. The long lever attached to the thumb-plate is intended to facilitate the insertion of deep stitches in plastic operations. The rotatory action of the instrument is the chief element of novelty, and this marks the difference between it and the holders now in general use. By slight movements of the thumb on the lever, complete control is obtained over the needle. Sir Spencer Wells' short scissor-shaped holder is suitable only for the introduction of large needles, and the ordinary spring instrument gives no variation of pressure at the points, except the slender accommodation obtained by covering them with soft metal.

[2] The reader may remember the three cases of malignant diphtheria quoted by Trousseau. First, that of a hospital colleague into whose mouth a small quantity of saliva was spurted by a patient when coughing, and who died in forty-eight hours: secondly, that of another physician, who died, also in forty-eight hours, after applying his mouth to the wound in the windpipe: and, lastly, that of a young medical man who died after an attack of diphtheria of seventy hours' duration, caught whilst sitting up for three nights with a patient.

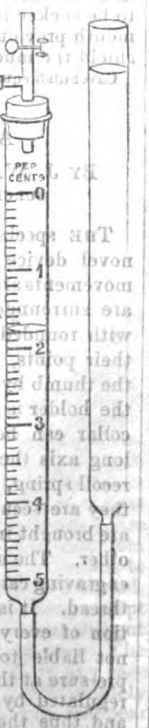
SOME NEW FORMS OF

APPARATUS FOR ESTIMATING NITROGEN IN URINE.

By A. W. GERRARD, F.C.S.,



DEMONSTRATOR OF MATERIA MEDICA AND PHARMACY TO UNIVERSITY COLLEGE.

THE apparatus now chiefly employed for estimation of nitrogen in urine analysis is that known as "Dupré's." It consists of an outer glass cylinder, to be filled with water; inside this cylinder is placed a glass tube graduated to show per cents. of urea. Nitrogen is evolved from the urine by an alkaline hypobromite, usually soda, and conveyed by a suitable arrangement to the inner graduated tube, water being displaced; on cooling the gas the inner tube is raised till the water it contains is level with the water in the outer vessel; pressure being thus balanced, the reading may be taken. The above instrument is undoubtedly as accurate as it is possible to make it, but has often impressed me as wanting in simplicity, and, moreover, on account of the delicate construction of some of its parts, is very liable

FIG. 1.

FIG. 2.

to fracture. Again, I have often seen an operator troubled to know when the zero was in its proper place, or levels correctly adjusted, and having to look through two columns of glass the graduations become obscure and the reading is made difficult. The instruments I have devised, and which will be best understood from the illustrations, are the result of a few experiments at simplification, and throughout I have aimed at keeping the highest degree of accuracy. Fig. 1 is a U-tube expanded at the top of one of its arms into a bulb, the bulb being designed to receive water displaced from the graduated arm. At the lower end of the bulb arm is a tubulus fitted with pinchcock for drawing off water. The graduated arm of the tube is marked in per cents. of urea, and fitted with a rubber cork and T-piece, connected with a wide-mouthed rubber corked bottle, to receive the hypobromite of soda. The small bottle inside the larger one is to receive the urine under examination. To work the apparatus the U-tube is filled with water to the zero line, the corks well fitted, and pinchcocks closed. The urine, 5 c.c. in inner bottle, is now upset into the hypobromite, the evolved nitrogen displacing the water in the graduated tube, causing the water to rise in the bulb. The bottle is now placed in cold water to cool the gas; then the pinchcock of the bulk arm is opened, and the water drawn off until it is exactly level in each tube; pressure being thus equalised, the percentage may be read. Fig. 2 is a simpler development of the first, consisting of two tubes communicating at their bases by rubber tubing. The tubes are kept fixed in spring clamps, so that they may be raised and lowered at will. The gas is generated exactly as in the other apparatus, pressing the water from the graduated into the plain tube, after the usual cooling has been effected by raising one tube or lowering the other, the level of the water is attained and pressure corrected. The percentage is now taken. The adoption of the flexible tube does away with the tubulus, and therefore the necessity for drawing off water, besides much cheapening the instrument. Both tubes are firmly fixed on stands, enabling them to be used with safety and facility, an analysis being completed in less than five minutes.

Both instruments are graduated with an allowance for all the usual corrections, so that the operator has simply to read his percentages of urea; in the drawings 5 per cent. only is indicated, but at the suggestion of Mr. Victor Horsley the instruments have been constructed to show 6 per cent. urea.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

SEAMEN'S HOSPITAL, GREENWICH.

A FATAL CASE OF STRANGULATED HERNIA; SAC OPENED; PORTION OF OMENTUM EXCISED; KNUCKLE OF INTESTINE REDUCED; AN UNDESCENDED TESTICLE AND SAC REMOVED; PERSISTENT FÆCAL VOMITING; DEATH; OBSTRUCTION OF KNUCKLE OF INTESTINE BY PEDICLE OF OMENTUM; REMARKS.

(Under the care of Mr. E. S. WEBBER, M.B. Cantab.)

W. P——, aged twenty-one, was admitted about one o'clock on the afternoon of September 4th. He said that he was at work in the morning, and about 10.30 A.M. was lifting a heavy weight when he felt something give way in his abdomen and come down into his scrotum. He could not get it back, and it caused him great pain. He said he had a rupture, but it had not been down for some years.

On examination it was found that a tumour occupied the left half of his scrotum and inguinal canal. It was not very tense, but could not be returned into the abdominal cavity, and the attempt caused him great pain. He was put to bed with an ice-bag over the scrotum, and had twenty minims of laudanum, which, however, he vomited almost immediately, and was sick again two or three times at intervals of about half an hour; the vomit was not stercoraceous. About 9 P.M. he was put under ether, and another attempt at reduction having failed, the sac was cut down and opened. It was full of omentum, and when this was lifted up a knuckle of congested intestine was seen; the omentum had a very thick pedicle, and that, together with the presence of an undescended testicle, seemed to be the sole cause of strangulation. The omentum was ligatured in four pieces and removed, and then the stump was returned into the abdomen. The intestine was easily returned and a finger could be passed up the canal into the abdominal cavity, where everything appeared perfectly free. The neck of the sac and the spermatic cord were next ligatured, and the sac and the testicle removed. Unfortunately the spermatic cord retracted from the ligature, so the wound had to be enlarged upwards, in order to find the cord again. When this was accomplished the edges of the wound were brought together. The operation was done with antiseptic precautions.

Sept. 5th.—The patient was a long time recovering from ether, and was sick several times; pulse good; has no pain and has also lost the anxious expression he had on admission;

Digitized by Google

urine drawn off. To take nothing but ice, and to have one grain of opium evey four hours.

6th.—Not sick until this morning, at 6.30, when vomit was stercoraceous; no pain in abdomen; is breathing comfortably; pulse good. Taking ice, and ordered one drachm of Brand's essence every two hours.

7th.—Wound dressed; looks quite healthy; has healed at lower part; slight tenderness and tympanites, but no pain; breathing chiefly thoracic; sick once last night (fæcal) and this morning vomited a little watery fluid; pulse 66 (regular, soft); tongue moist.

8th.—Sick three times (fæcal); feels well; no pain; less tenderness over wound, and less tympanites; tongue clean; pulse good.

9th.—Sick once (fæcal); passed flatus yesterday for the first time; feels well; no pain over abdomen; tympanites very slight; tongue moist; pulse good. He was put on beef-tea.

10th.—Sick twice (fæcal); wound dressed and looking well; there is very slight tenderness over it and at the upper end is a little localised hardness, probably the stump of omentum; the remainder of abdomen quite flaccid, and palpation does not cause any pain; passes flatus; has been ordered some milk and soda-water, which he fancied very much; looks well; pulse good; tongue slightly dry; sleeps well.

11th.—Sick three times yesterday (fæcal); a little pain and tenderness over the upper part of the wound; passes flatus; has a somewhat anxious expression; pulse quick and feeble; tongue dry and brown. The milk was discontinued, and he was ordered to take beef-tea and six ounces of brandy.

12th.—Sick once (fæcal), but a smaller quantity; passing flatus; no pain or tympanites; tongue moist; pulse quick but stronger; feels hungry; sleeps well.

13th.—Sick once (fæcal); passing flatus; tongue furred and moist; pulse good; no pain; feels hungry; sleeps well; wound dressed; lower two-thirds healed; upper third nearly healed, and hardness can still be felt at the upper part.

14th.—Not sick at all; feels better; passes flatus; no pain; no action of the bowels, but feels a desire to have an action; pulse good; tongue furred, moist.

15th.—Not sick; still passes flatus.

16th.—Very sick once (fæcal); enema (soap and water) given yesterday was returned unchanged; tongue moist and clean; pulse good; slept well; says he feels well; passes flatus; no pain; wound nearly healed; antiseptic dressing left off.

17th.—No sickness; passes flatus.

18th.—Sick once (fæcal); opium reduced to two grains a day.

19th.—No sickness.

20th, 21st, and 22nd.—Sick once (fæcal); soap and water enema with an ounce of castor oil given on the 25th, brought away a few scybala.

24th.—Sick twice (fæcal); is looking ill; pulse small and quick; tongue dry; no pain; sleeps well. To be fed with half an ounce of milk every hour by the mouth, and the following nutritive enema every three hours: two ounces of essence of beef, half an egg, half an ounce of brandy, ten drops of tincture of opium and ten grains of pepsin.

25th.—Was fed yesterday with enemata as above; retained them all; was slightly sick this morning (fæcal); passes flatus; tongue clean, a little dry; pulse regular, small.

26th.—Retained all the enemata; was sick three times yesterday (fæcal); milk discontinued; to have nothing by the mouth except a little ice; abdomen since yesterday morning a little swollen and tense; no pain; pulse regular, quick and small; tongue clean and dry; passes flatus. To have one grain of opium every four hours by the mouth, and opium in enema reduced to three minims.

27th.—Retained all the enemata; no sickness; abdomen more distended; no pain; tongue clean and dry; pulse regular, quick (100), small; passes flatus. Taking half an ounce of milk every hour.

28th.—Returned one enema; was sick once yesterday (fæcal); abdomen distended; no pain; passes flatus; pulse still weaker; tongue furred, moister.

29th.—Retained all enemata; no sickness; abdomen very tense; no pain; almost pulseless; hands and feet cold. Gradually sank and died at 12.30 P.M.

Necropsy, twenty-fours after death. — On opening the abdomen, the omentum, devoid of fat, was seen stretched tightly across the intestines, and was attached by the pedicle to the abdominal wall in the situation of the upper angle of the wound made by the operation. On cutting through the omentum, there were some signs of recent peritonitis, the intestines having lost their lustre and a few flakes of lymph being seen, but there was no fluid. Attached to this pedicle of omentum was a tumour the size of a small hen's egg, which corresponded to the patch of hardness felt there during life, and appeared to be a knuckle of intestine bound there by adhesive inflammation. On starting with the rectum and tracing the intestine backwards, the large intestine was found to be fairly normal; but the small intestine collapsed up to the point, a distance of two feet from the ileo-cæcal valve, where it entered the tumour mentioned before, while on emerging from it the remainder was enormously distended. A ligature was put round each portion of the gut emerging from the tumour, the gut cut through, and the tumour removed from the abdominal wall. On examination it was found that the finger passed quite easily down each end of the gut, but could not get past the point where the gut was bent on itself, the angle of curvature being a very acute one. On cutting open the gut, it appeared simply congested. There had been adhesive inflammation going on between the peritoneal surface of the gut and the omentum, and it was difficult to separate them at this point, the omentum covering the gut by about a quarter of an inch in thickness.

Remarks by Mr. WEBBER.—The chief interest in this case lies in the fact that the patient lived for twenty-four days after the operation with almost continuous fæcal vomiting. The necropsy showed that he had obstruction caused by the binding down of a piece of gut with the pedicle of omentum to the external wound, but until then there was no certainty of diagnosis, as up to the last three days of his life the absence of all pain, the cheerful expression of countenance, the flaccidity of the abdomen, and the continual passage of flatus, all pointed to a state of paralysis of the gut rather than anything else. The continuous fæcal vomiting, however, was looked upon with suspicion, and I think in cases where this symptom goes on for more than ten days after an operation for strangulated hernia it should be an indication to open and thoroughly explore the abdomen, as obstruction after that length of time is not probably due to a continuance of paralysis of even an intensely congested piece of gut, and should be attributed to some other cause.

DUNDEE ROYAL INFIRMARY.

ACUTE CHOREA; EXTREME DEGREE OF JERKING; NIGHT SCREAMING; INCONTINENCE OF URINE; CHLOROFORM INHALATION; ADMINISTRATION OF CONIUM JUICE; RECOVERY; REMARKS.

(Under the care of Dr. SINCLAIR.)

FOR the following notes we are indebted to Dr. D. J. Reid, late house-surgeon.

D. F——, aged twelve, was admitted on Aug. 31st, 1883. A year ago he had a mild attack, which lasted three months. The present attack was attributed to a fright from his having been put into a dark hole by some boys. Before the jerks came on he had some pains in his limbs.

There was a decided rheumatic family history, though the father and mother never had rheumatism. A sister, now twenty-five years of age, had acute rheumatism with cardiac lesion when fourteen years old. The paternal grandfather and a paternal uncle had rheumatic fever. The maternal grandmother suffered so much from chronic rheumatism that she had great difficulty in managing her own children. The present attack came on six weeks before admission, and since then he had had no control over his limbs, and his speech has been affected. For nearly six weeks before admission he had been under treatment, and had been taking arsenic and bromide of potassium, but without any improvement.

On admission, and when first seen in bed, he was tossing about and did not seem to be able to lie still for a moment. His upper and lower limbs were in constant movement, especially the latter. The head was at times jerked to the one side and at times to the other, and occasionally backward. The whole body was from time to time bent backward like a bow. If asked to protrude the tongue he jerked it out, sometimes to the one side and sometimes to the other. The muscles of expression also participated in the movements, the eyebrows being raised from time to time, but on the whole the face was placid. There was an auriculo-

Digitized by Google

systolic murmur at the apex. Pulse weak. Temperature 99·8°. The patient was ordered a draught containing ten grains of chloral hydrate and fifteen grains of bromide of potassium.

On Sept. 1st four drops of arsenical solution were ordered to be taken four times a day, and, being restless at night, the draught was repeated. Temperature normal. At midnight, the patient having been for some time in a fearful condition, tossing about and screaming at the very pitch of his voice, twelve grains of chloral were given; he, however, spat it all out. Chloroform inhalation was then tried, until he became quiet.

2nd.—After the chloroform inhalation he remained quiet until 2 A.M., when he again began to toss about and scream as before. To-day one drachm of succus conii was ordered to be given four times a day, along with the four-drop dose of arsenical solution. Evening temperature 99·8°.

3rd.—Evening temperature 98·4°. Patient has been a good deal quieter to-day.

4th.—Morning temperature 98·4°; evening temperature 98·4°.

5th.—Has not had a draught since the night of the 2nd. Choreic movements less.

6th.—Nurse states that he has had incontinence of urine since the 3rd. The arsenic was stopped to-day, and he was ordered to have ten drops of tincture of belladonna along with the drachm of succus conii four times a day.

14th.—Choreic movements diminishing. Incontinence continues.

26th.—Jerks almost stopped, but incontinence continues. The dose of belladonna tincture was increased from ten to fifteen drops four times a day.

27th.—Incontinence less.

Oct. 3rd.—No incontinence for the last five days; scarcely any twitching except to a slight extent about the mouth. To get up to-day.

22nd.—No purring tremor over the heart, and no cardiac murmur. The apex beat, however, still displaced downwards; no jerks. Discharged well.

Remarks by Dr. SINCLAIR.—It will be observed that on both the paternal and maternal side, but especially the former, there was a well-marked rheumatic tendency, although the patient himself never suffered from any rheumatic affection beyond the pains in the limbs complained of before the onset of the attack for which he was under my care. This case was without exception the most aggravated attack of acute chorea it has been my lot to see. The poor boy's sufferings were most painful. Arsenic and bromide of potassium in full doses had been tried before I saw him, but without any effect. It will be observed from the clinical record that although he was so ill as to require the administration of chloroform on the day after admission he immediately improved after four one-drachm doses of conium juice, and he continued to improve steadily under its use. It was not found necessary to resort to the enormous doses recommended by some authors, and derided by others. Ten-minim doses of tincture of belladonna appeared to have no effect on the incontinence of urine, which rapidly ceased on the administration of fifteen minim doses four times a day. The cardiac murmur also disappeared under treatment. On October 21st, 1884, the patient's mother stated there had been no return of the disease since the boy left the infirmary.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Lumbar Nephrectomy.

AN ordinary meeting of this Society was held on Tuesday last, Dr. George Johnson, F.R.S., President, in the chair. The discussion on Mr. Morris's paper lasted the whole evening, which was prolonged for half an hour beyond the usual time.

Mr. HENRY MORRIS read a paper on a successful case of Lumbar Nephrectomy for Renal Calculus. A labourer, aged thirty-five, who had suffered from well-marked symptoms of renal calculus of the right side since the end of 1881, and had been under the care of Dr. Douglas Powell at the Middlesex Hospital, came again under treatment in October, 1883. In November, 1882, Mr. Morris had explored the kidney digitally and with the probing needle, but did not detect the stone. On October 24th, 1883, the exploration was repeated, but again failing to detect the stone the kidney was removed through the lumbar incision. The patient made an uninterrupted recovery, and at the present time is at hard work as a charcoal-burner, and "is as well as ever he was in his life, and able to work without the slightest inconvenience." The kidney excised was of normal size and appearance, and the secreting structures were found by Dr. Coupland on microscopical examination to be quite healthy. The organ, however, was harder and tougher than usual, and contained a rounded rough calculus about the size of a marble. Careful daily examination was made of the urine by Mr. Paul, both before the nephrectomy and for more than six weeks after the operation, so that the rapidity and power with which one kidney can take on the whole of the excretory function was shown in a table which formed part of the paper. The results are equivalent to those of a simple physiological experiment, because a healthy kidney (so far as its excreting substance went) was removed, and a healthy one was left behind. A comparison was made between the lumbar and the peritoneal methods of nephrectomy. It was shown that the arguments which have been used in favour of the peritoneal operations were more theoretical than practical, and that if logically followed out they were likely to lead to pernicious results. The conclusion arrived at was that lumbar nephrectomy is, as a rule, the better operation, though there are exceptional circumstances and certain diseased conditions in which the abdominal method is preferable. In nephro-lithotomy the lumbar incision, and that only, ought to be employed. In judging of the condition of the opposite kidney to the one to be removed, we have to depend upon the general symptoms of the case and upon the amount of urea daily excreted. But it is not correct to infer that the kidneys are diseased because they excrete a daily average quantity of urea even less than half the standard quantity. Persons who have long been living an invalid life, and who have lost much flesh, may, with perfectly sound kidneys, only pass from thirty to thirty-five ounces of urine a day, and eliminate not more than from 1 to 1·3 per cent. of urea in this quantity of urine.—The PRESIDENT supposed that the chief points for discussion would be the relative merits of the peritoneal and lumbar methods of nephrectomy.—Mr. THOMAS BRYANT thought the case a valuable addition to the surgery of the kidney, and presented many interesting points for discussion. It was, no doubt, a physiological experiment as to the value of a kidney, and proved that one kidney, if good, would very soon take on the action of both kidneys. The question of diagnosis was very important; careful manipulation and exploration had failed to detect the stone on two separate occasions. In all cases of suspected stone the operation of nephro-lithotomy would be undertaken as one of an exploratory kind before it could be anything more, for the surgeon was perfectly justified in exploring the kidney when the symptoms pointed to a calculus. The suggestion of incising the pelvis of the kidney for the purposes of searching was a good one, and not much harm could come even if incision be practised through the parenchyma of the kidney. He had no doubt whatever that the lumbar operation was certainly *the* operation for nephro-lithotomy, for the reasons that the pelvis of the kidney could be better got at from behind than from the front, and a most thorough investigation could even be carried out at this site. His feeling was greatly in favour of the lumbar incision from all points of view. Where the diseased kidney is greatly enlarged the employment of the peritoneal section was perhaps called for. In a measure the removal of a kidney had been an accident, as in cases where other organs were supposed to have been the cause of the abdominal tumour, for which the abdominal section had been practised. It was a question whether, in pyonephrosis or hydronephrosis removal of the kidney was required. Would not drainage and washing out effect all that was necessary? Would a discharging sinus, continuing for years, justify the operation of nephrectomy? He referred to three cases in which he had respectively removed eighty-eight ounces of pus, one quart of matter, and thirty-six ounces of pus, all of which were in a favourable state, although the ultimate recovery was slow. He had not yet removed a kidney, and doubted whether he ever should do so.—Mr. WHITAKER HULKE said that, like Mr. Bryant, he had not practised nephrectomy, but had some experience of nephro-lithotomy, and cutting into the kidney. He felt sure that the lumbar

Digitized by Google

incision was certainly preferable to the peritoneal section. He agreed with Mr. Bryant that if the tumour were large the peritoneal section would be best if it were the intention to remove the whole kidney. But in cases of hydronephrosis and pyonephrosis the lumbar incision and drainage would obviate the necessity of the peritoneal section. In cases of extirpation of the kidney by the abdominal method a perinephritic collection of pus might be met with after removing the kidney from its capsule, the inevitable result would be peritonitis. He referred to cases in which the symptoms pointed to stone, and in which no trace of calculus could be made out by any means or at any time. A boy aged nineteen, who was the subject of frequent attacks apparently of renal colic, had been unable to earn his living, and Mr. Hulke had made an examination of the kidney, adopting the method of a longitudinal incision parallel with the outer border of the quadratus lumborum, but neither by manipulation, nor any method of exploration, either of needling or otherwise, was any certain indication of the presence of a stone made out. He considered that a limited incision into the pelvis of the kidney was not only justifiable, but ought to be made when other methods of exploration had failed.—Mr. KNOWSLEY THORNTON congratulated Mr. Morris on his escape from one of the calamities of surgery, seeing that a kidney so obviously healthy as the one removed had been followed by no evil consequences. He could not but think that so small a calculus might have been removed and the kidney saved. One of the great advantages of the abdominal section was the freedom with which one might incise without any great danger of ill effects ensuing. He noticed that Mr. Morris's patient had been lying in a damp barn, and he questioned how much this sudden chill was one of the most common causes of the formation of stone. He could not agree that the ureter drawn out of the abdominal wound might lead to obstruction of the intestines, and thought that if left untied at the back of the abdomen there was more danger of sloughing and septic inflammation resulting. The urine was ammoniacal and offensive, and the ureter had become more or less sloughy in cases under his care, but he considered that the ureter was equally likely to undergo similar changes if left in the lumbar region. He thought that bringing out and keeping the ureter separate from the other tissues was by no means an useless precaution. He advocated the abdominal method as a means for removing calculi from the kidney, although he was sure that he would be in a minority of one. He narrated a case in which he had removed a calculus by this method. He gave him the advantage of examining the other kidney. Everything hinged upon the fear which surgeons had of wounding the peritoneum. He would just as soon, or rather, wound the peritoneum than any other tissue of the body. He had seen a case with a fistulous opening in the loin getting steadily worse, and only saved his patient by timely nephrectomy by the abdominal method. Incontinence referred to by Mr. Hulke there need not necessarily have been a fatal case; no doubt a perinephritic abscess was a serious complication of the abdominal section, but efficient washing and drainage of the peritoneum might prevent a fatal result. He showed that statistics were in favour of the lumbar incision, and he felt sure that the abdominal section, if fully tried, would give the best results. In many cases the symptoms were no guide to the state of the other kidney. He was of opinion that examination by the abdominal section would give good indications of the state of the kidney. It would have been possible to detect the stone in Mr. Morris's case if the abdominal method had been employed.—Mr. CLEMENT LUCAS agreed with most of the conclusions of the paper, and was glad that Mr. Morris had adopted the method of an oblique combined with a vertical incision, which he (Mr. Lucas) had advocated. It was a misfortune, however, that the kidney should have been removed. He asked whether the peculiar method of manipulation of pressing the kidney further against the psoas muscle, as practised by Dr. Hawes, had been employed. Nephro-lithotomy, followed by nephrectomy, had been the stages employed by him in all cases. The urine was normal throughout, and in every respect in some cases of calculus which had been under his care. In one case the boy, at the age of three years, had been cut for stone in the bladder. Mr. Durham had had a similar experience. These were presumptive evidence in favour of a calculus if the person had been previously cut for stone. In the case of strumous pyelitis he thought that the pus in the urine was rather in excess of the pain, whereas the opposite pertained in cases of calculus. The fact that the substance of the kidney was insensitive was important, and renal colic was due to the presence of foreign material in the pelvis or ureter. We knew that clots of pus and of blood give precisely the same pain as the passage of a calculus. Reference was made to a case under the care of Mr. Thomas Smith in which sudden death had occurred, and the autopsy showed that an enormous stone had blocked each ureter, that there was a calculus in the gall-bladder, and a sarcoma of the wall of the heart. With regard to drainage through the loin, he was not sanguine as to the ultimate result in the great majority of cases. In those instances which he had witnessed a subsequent nephrectomy, though necessary to save the patient, was always, however, successful. He should never adopt the abdominal section except in cases of large solid tumours of the kidney. The treatment of the ureter was by no means a settled question. He referred to a case in which there was blood and pus in the urine with symptoms of a calculus; at an exploratory operation the cellular tissue was adherent at one spot, and here there was fluctuation; aspiration showed it to be a pultaceous abscess the size of a walnut, which was opened and drained.—Mr. W. HULKE said that in the case he had narrated with the exception of the presence of crystals of oxalate of lime the urine was normal.—Mr. R. BARWELL spoke of the occurrence of severe paroxysms of pain without any sign of disease of the kidney being detected by any method of examination. If the kidney had not been removed by Mr. Morris, the man would still have suffered from the pain, and so, in his opinion, the removal was not a misfortune. The case of a woman aged forty-four, who suffered from paroxysms of pain, and who had passed much pus and blood in the urine, was narrated; the kidney was very loose and movable. He made an exploration by the lumbar method, but found no disease; the patient remained free from pain for three weeks, but after the healing of the wound the pain returned, and some time later the kidney was found to have escaped into the subcutaneous tissue, but no pus or blood was passed in the urine, though much pain was still experienced. After he had replaced the kidney in the abdomen the patient grew weary, and went away from the hospital. The ureter, like the ovarian pedicle, might cause obstruction of the bowels. In one of three cases the ureter had sloughed; he considered that there was no great advantage in tying the ureter. That renal tumours of a large size could be removed through the loin he felt sure, though difficulties had been experienced by him recently.—Mr. F. C. LARKIN said that in 1869, owing to a case of renal calculus, and to a case of rupture of the renal artery, where the man had only one kidney, he had undertaken a series of experiments on rabbits to prove that if one kidney were extirpated the other kidney could take on all the renal functions. On Oct. 9th, 1869, he had read a paper on Nephrotomy.—Sir SPENCER WELLS spoke on the question of diagnosis; he referred to one rather easy way of detecting a stone in the kidney, a method advocated by Simon, in which the hand was passed into the rectum with a view to the diagnosis of ovarian tumours and outgrowth from the uterus. In a case which was diagnosed as one in which both ureters were blocked by stones, Sir Spencer Wells had found the tumours to be ovarian. He considered that rectal exploration was a mode of gaining information much more simple than any method requiring incision of important structures. Whether it was better to explore through the loin or by the abdominal method was still a question, and many more accurately recorded cases were needed before the mind could be made up on it.—In reply to Mr. MACNAMARA, Sir Spencer Wells said that he had felt a stone by the rectal method.—Mr. MORRANT BAKER considered that the rectal method involved considerable danger. He had had to do with cases requiring renal exploration on three occasions, but his experience led him to believe that we had not yet facts at our disposal on which we could say which was the better operation, the lumbar or the abdominal. He would not be astonished if there were a reaction in favour of the peritoneal section, although his cases were all operated on by the lumbar method. Another point which deserved consideration was whether the fingers should be passed between the kidney and the capsule rather than between the latter and the peritoneum; it was true that in this modification more ligatures, tearing, and oozing would be expected; but he questioned whether the kidney might not be removed more safely than by any other means. In all his cases previous nephrotomy had been performed, and the cases grew steadily worse, so that nephrectomy was required. The first case was that of a girl, aged ten

Digitized by Google

years; and she lived a year after the operation of nephrectomy. He thought that the fact of her having only one kidney might have led to her death, for in an illness it was possible that such patients having but one kidney ran a considerable risk of life.—Mr. ARTHUR E. BARKER considered that we should not lose sight of a distinction which ought to be drawn between the amount of disease of the kidney. He said that everything depended on the state of the kidney. If there were a fistula which constantly discharged a daily quantity of ten to fifteen ounces, great risks of phosphatic deposit which tended to block up the sinus were run, and such obstructions had been known to produce high febrile action; whereas, if the fistulous opening gave but very little discharge, there was far less chance of serious accidents arising.—Mr. MORRIS, in reply, said that no doubt the case was a misfortune from a surgical point of view, though the removal of the kidney was not a misfortune for the patient. With regard to methods of exploration, that of incision into the kidney had at that time not been thought of by him nor suggested to him by his reading. The burden of his paper was to show that such an incision should be employed. With regard to the ureter, he thought that Mr. Thornton's argument was its best refutation, for if sloughing of the ureter did not occur by detaching it from the bed of connective tissue in which it lies, it would be astonishing, seeing that the branches of the parietal arteries, and of the vesical and renal arteries, were its sources of blood-supply. In Dr. White's case the ligatures did set up obstruction and excited an abscess at the site of the pedicle, though the case recovered by the pus draining away through the ureter and bladder, and not by discharging upwards through the abdominal wound. These considerations formed the strongest argument in favour of the lumbar incision. Mr. Morris had not the least fear of the peritoneum, though he had the highest respect for it, and he felt that it was a land on which he had no right to trespass whilst the same conclusion might be arrived at by other means. By compressing the kidney against a table he had been unable to detect the stone. Mr. Bennett May had sent him word of the removal of a scrofulous kidney weighing 14 oz. through the lumbar incision. Four days later the patient died, and the other organ was concealed in fat, and its condition could not be made out at the autopsy until it had been enucleated from its bed of fat, when it was found to be in a caseous state. In this case the patient lived four days without any renal tissue, and up to the time of operation she was secreting less than eighty grains of urea per day. Dr. Goodhart had collected statistics for him, and showed that of 4632 autopsies there was but a single instance of a solitary kidney. It was true that nephrectomy had been performed in a case where there was but one kidney. But what sort of case was this? It was one in which there was deformed external genital apparatus, the vagina and the uterus being absent. He had a gentleman under his care who discharged 10 oz. of urine in the loin, and this gave him no inconvenience, and he doubted not that his patient was in a better condition than if the kidney had been removed. On many occasions he had resorted to rectal examination, but he had considered it to be less valuable than it seemed to be, for the reason that the hand was so cramped. He had seen a case of ruptured rectum due to digital exploration. Replying to Mr. Larkin, he reminded that gentleman that about the beginning of the century Dr. Blundell had shown that a rabbit was able to live without a kidney as well as without a uterus.

MEDICAL SOCIETY OF LONDON.

Anæsthetics.

AN ordinary meeting of this Society was held on Monday last, Mr. Arthur E. Durham, President, in the chair.

A case of Cheiro-pompholyx was shown by Dr. FARDEN.

Mr. BRAINE read a paper on Anæsthetics. He said that for brief operations nitrous oxide gas was the best, and for prolonged operations the gas followed by ether. Many anæsthetics caused death through the circulation; these were chloroform, bichloride of methylene, dichloride of ethydene, ethylic ether, and many other members of the chlorine series. Whereas ether and nitrous acid caused death only through cessation of respiration in the first place; with the larger group death begins at the heart and is instantaneous. In cases where the failure occurs first at the lungs, artificial respiration might produce a good result, although more than a minute had elapsed. With regard to the bichloride of methylene, he would like to know how much vomiting was met with. He considered that vomiting after ether was often caused by flatus. One of the best remedies for hiccough after the administration of anæsthetics was green tea without milk or sugar; dilute solution of hydrocyanic acid was also valuable. Nitrous oxide was said to cause congestion of the face and head, but in his opinion there was no congestion; a careful investigation would show that the vessels diminish in calibre and that the blueness was due to alteration of the blood and not to dilatation of vessels. He thought that the dose of "laughing gas" which was now given afforded an explanation of the want of exhilaration which characterised its present use. He had given gas to partially intoxicated people without producing any excitation; it was important not to allow air to mix with the nitrous oxide. He advised that the room should be kept as quiet as possible, and that no one should speak, even in a whisper, whilst gas was being administered. He was sure that patients recovered the sense of hearing before they recovered the sense of pain, and from experiments on himself he concluded that the auditory perceptions were decidedly altered. Pregnant women could take the gas well even when they were eight months advanced in gestation. "Gas" caused no derangement of lactation. Patients suffering from hemiplegia and chorea were able to take "gas" with impunity. In cases of phthisis the nitrous oxide could be used with safety if the disease were not too extensive, though even then it could be used with the necessary precautions. Great age was no bar to the administration of nitrous oxide; he had anæsthetised a lady aged ninety-four. Patients were found to require less anæsthetic early in the morning than later in the day, as a rule. Faintness must never be allowed to set in, and so attention to matters of diet was necessary. He advocated the examination of the patient prior to the commencement of the administration, with a view to rendering the patient less nervous. Patients should be allowed to keep the eyes open, so as to inspire confidence. Attention to the state of the teeth was of the greatest importance; a whole set of false teeth were the least dangerous. Nasal tubes were not approved of. It was no doubt of great importance never to get in the way of an operator. If the administration were properly carried out struggling should not occur. He had not seen fatal results follow the use of ether in cases of albuminuria, as the Americans asserted. Ether had not produced any ill effects in his hands. In cases of relaxed uvula the sitting posture, with a forward position of the head, was advocated. If there were a free choice in the posture of the patient, he preferred that of lying on the side with the arm drawn under the trunk. The importance of raising the lower end of the bedstead in cases of tendency to failure of the pulse and respiration after the anæsthetic was laid stress upon. Two minutes and forty-five seconds was the time required to completely anæsthetise when gas was used. When bronchitis occurred he believed it was due to exposure to cold draughts of air, and not to the ether. The occurrence of the thick mottled rash about the neck took place with every anæsthetic except nitrous oxide. Nitrite of amyl in capsules was very useful in cases where failure of the circulation was feared during the use of chloroform. A polypus forceps was the best instrument to draw the tongue out. Absolute immobility was essential in warding off vomiting.—Mr. BAILEY thought nitrous oxide was the easiest anæsthetic to administer. The dangers of the administration of the various anæsthetics had not been drawn attention to by Mr. Braine; although "gas" was best for brief operations, yet it might be used for a long time, even forty minutes, though this was not advisable. Bichloride of methylene did not exist, for the mixture which was so named was very unstable. Dichloride of ethydene was a cardiac depressant, and he should not recommend it, although Clover had considered it a good anæsthetic. Artificial respiration was the remedy to be immediately resorted to when the respiration or circulation suddenly failed. He deprecated the strapping of a patient down to the operating table. A process of selection of cases would be very serviceable. The perfection of anæsthesia would be reached when we had separate agencies for preventing motion, abolishing sensation, and producing unconsciousness. The mortality from the administration of bichloride of methylene was about the same as that from chloroform—about 1 in 4000.—Dr. GEORGE EASTES said that he had used chloroform, the A.C.E. mixture, the

Digitized by Google

nitrous oxide gas, and ether. From his first experience at Guy's Hospital he was inclined to think chloroform, as roughly used on Skinner's inhalers, as a safe mode of producing anæsthesia. But after having witnessed four deaths from the administration of the vapour of chloroform, he became less and less satisfied with this anæsthetic. M. Paul Bert, some twenty years after Clover had drawn attention to the matter, spoke of a 6 per cent. vapour of chloroform as a safe anæsthetic. But this percentage might give rise to lethal effects in man. He believed that the A.C.E. mixture was equal to most of the emergencies of an anæsthetist's practice. Clover's apparatus was recommended for the administration of ether. The value of nitrite of amyl in bringing a patient to consciousness was very great.—Mr. JENNINGS had made a series of experiments on dogs, in order to obtain a correct estimate of the danger from chloroform inhalation. Death may arise from asphyxia, or be due to paralysis of the heart. In the former mode of death the chief cause at work was the paralysis of the larynx, since if the epiglottis were drawn down like a valve no air could enter. But traction on the tongue draws the epiglottis forwards only a very little, and so he advised the use of an artery forceps for keeping the epiglottis forwards and a pair of curved artery forceps for use on man were exhibited. In dogs it was difficult to know when the heart had stopped; he had brought dogs "round" when the pulse had ceased for some time, and even as long as for eight minutes. In his experience ammonia and atropine were of much value in relieving cardiac depression. The use of morphia and atropine prior to the administration of chloroform was thought desirable.—Mr. WALTER PYE said that we could not argue from dogs to man, as there was really no analogy between the two cases. Chloroform was very fatal to dogs.—Mr. MILLIGAN referred to the possibility of inducing transient anæsthesia by breathing deeply and frequently.—Mr. BARROW considered that the variety of the surgical operation ought to influence the rate of administration of ether. In brief operations he would administer ether more rapidly. For a long operation the patient should be more slowly anæsthetised.—Mr. ADAMS FROST made some remarks on the anæsthetic value of muriate of cocaine; the occurrence of vomiting was frequently fatal to good results in ocular operations. A 4 per cent. solution of cocaine for small operations, such as "needling" the capsule of the lens, was used three times with success, but a narcotic effect ensued, all the patients sleeping for five hours at a stretch.—Dr. FELIX SEMON referred to cocaine as a local anæsthetic in operations on the nose and throat. A 4 per cent. solution had been used, but a very much stronger one, such as a 20 per cent. solution, was much more efficient.—Dr. D. W. BUXTON said that his experience taught him that dogs were peculiarly susceptible to chloroform. With regard to bichloride of methylene, which was a mechanical mixture of chloroform and alcohol, he said it was brought before the public under false colours. He thought that it caused less nausea and less vomiting, but the narcosis produced from it passed very rapidly away. He was inclined to believe that laryngitis and bronchitis were induced by ether. Chloroform was a safer anæsthetic than ether for children. Nitrite of amyl acted like chloroform, and dilated the arterioles.—Dr. RICHARD PARAMORE referred to the dabbling of the public in dangerous anæsthetics.—Mr. BRAINE, in reply, maintained that nitrous oxide was, in inexperienced hands, difficult to give effectively. It was important to render the patient thoroughly insensible before leaving off the nitrous oxide and commencing the ether. Sometimes with nitrous oxide he had not observed any change of colour.

ACADEMY OF MEDICINE IN IRELAND.

THE opening meeting of the Pathological Section for the session 1884-85 was held on Friday, Nov. 7th, Dr. FOOT, President, in the chair.

The PRESIDENT delivered an interesting and suggestive inaugural address on the Cultivation of General Pathology.

Mr. KENDAL FRANKS read a paper on a case of Intussusception of the Small Intestine, which had occurred in a man under his care. Some of the symptoms of that affection were present, but on the whole the diagnosis was most obscure. An exploratory abdominal incision was determined on. An intussusception, measuring eleven inches in length, was found in the right iliac region, and various methods of reduction were attempted, but without success for a considerable time. Part of the gut was almost gangrenous, and the peritoneum had given way in places. These had to be sutured. The patient died a few hours after the operation. The chief points of interest in the specimen exhibited were, in the author's opinion:—(1) The seat of the intussusception in the small intestine, far above the ileo-cæcal valve; (2) the difficulty of diagnosis; (3) the question of operation in reference to adhesions.—The PRESIDENT remarked that perhaps the difficulty of reducing the tumour after it had been exposed was that the natural process of cure had set in and adhesions between the surfaces of the entering and the returning cylinders were being effected. Possibly, if it had been left alone a little longer the natural process of suppuration and sloughing would have ensued.—Dr. H. KENNEDY observed that the cases of intussusception which he had seen had been invariably chronic in adults and acute in children. He had lately had a case which began with extremely acute symptoms, and yet, after five weeks, a post-mortem showed that the intussusception must have been of three or four years' duration. He had seen six cases of the affection, and they all commenced at night, and, as a general rule, the patients had eaten something out of the way for supper—such as cockles with porter, a salt herring with butter-milk, &c. Having regard to the safety with which the once formidable operation of opening the abdomen was now performed, he thought that cases of this sort should be surgically met infinitely more early than they had been.—Professor BENNETT noted that several of the injections were followed by hæmorrhage. He had often dealt with cases of intestinal obstruction and had got them well under by the use of enemata, and he had not known the bleeding to occur after the enema, except in cases where there was an intussusception.—Dr. WALTER SMITH said the diagnosis of intussusception was extremely difficult, and they should be thankful for all the light that they could get on the subject. The author of the communication had stated that he had inferred an obstruction in the small intestine from the occurrence of indican in the urine. If that conclusion were justified it would be a great help to diagnosis; but he did not think their knowledge of physiological chemistry as regards this point was as yet sufficient to establish a definite relation between intestinal obstruction of the small intestine and the formation of indican. Immense quantities of indigo were found in the urine in cases in which there was no intestinal obstruction. He had found it to occur in cases of pleuritis, and in one case of peritonitis which came under his observation.—Mr. FRANKS, in reply, did not think any spontaneous cure had commenced in his case. At the place where the intussusception took place there were no signs of lymph at all, and if sloughing had taken place it would have been only a sign that the patient was a stage nearer the grave. In the two cases of which he had spoken the symptoms were diametrically opposite. The case which turned out to be chronic had the rigidity of the abdominal muscles and peristalsis, while the acute case had the distension of the abdomen and no peristalsis.

Mr. WHEELER exhibited and described a Tumour which occurred in the Hypogastric Region of a female, aged nineteen. She was of a fair and ruddy complexion. The tumour was firmly fixed in the region of the pubes, the superior portion of it being rather movable. There was an enlarged gland in the groove, and on the surface of the tumour was a fungating mass. The tumour had grown within a period of thirteen months, and the patient was admitted into the City of Dublin Hospital in the end of last July. An examination with the sound proved that the uterus was perfectly free, and that perhaps the bladder was free also, although there was not so much certainty as to the latter. There were no constitutional symptoms; she ate well, and her excretions were healthy. The tumour was excised by means of two lateral excisions. Severe hæmorrhage took place, which did not appear to proceed from blood-vessels, but from sinuses within the tumour, which sprang from the pubes and lay on the peritoneum. It weighed 16lb. 6oz. Dr. Abraham had found it to be a spindle-celled sarcoma. Neither the bladder nor the peritoneum was engaged. Such a tumour had not been found before in females. The patient died within four or five weeks after the operation.—Dr. FITZGIBBON said he was present at the operation, and its expediency was concurred in by all who saw it. The process of removal was comparatively easy until the deep attachment of the pubis

Digitized by Google

was reached, and then there was considerable difficulty. He believed the hæmorrhage which then occurred was the cause of the subsequent collapse of the patient. Mr. Wheeler removed the tumour without opening the peritoneal cavity or inflicting any necessarily fatal injury on the patient.—DR. EVELYN LITTLE asked how it was that a tumour which, according to Mr. Wheeler's description, started from behind all the muscles of the abdomen, and which only adhered to the front of the pubes, did not perforate the abdominal parietes.—Mr. WHEELER, in reply, said the tumour did not grow from the front of the pubes, but from behind the recti muscles. The gland, when fresh, had a very different appearance from the tumour, being then like a healthy kidney. An Esmarch bandage was applied to the girl's leg. He did not think it was from loss of blood she died.

Mr. LENTAIGNE exhibited a specimen of an Aortic Aneurysm. It was of a small size, and occurred in one of the sinuses, and was taken from the body of a woman who died suddenly in a Turkish bath. The pericardium was intensely distended with blood, and there was a considerable amount of atheroma and some alteration in the walls of the heart. The only lesion was the aneurysm, which was very small, about the size of a hazel nut.

Reviews and Notices of Books.

Elements of Surgical Diagnosis. By A. PEARCE GOULD, M.S., M.B. Lond., F.R.C.S. Eng., Assistant Surgeon to the Middlesex Hospital, &c. Pp. 584. London: Cassell and Company. 1884.

A WORK on surgical diagnosis is of the same use to the clinical student as demonstrations of anatomy are to the anatomical. Systematic text-books are excellent in their way, but for the beginner they are too descriptive and not sufficiently directive. Mr. Gould has supplied a guide to diagnosis which is sure to be immensely popular with students, for in addition to the careful arrangement and skilful comparison of facts, the text is written in good style—a by no means easy task where a large amount of information has to be compressed into a comparatively small space. Some of the pages show traces of what may be termed writing against time, notably those of the first chapter, which treats of the general features and landmarks of surgical cases. There is in consequence a certain want of accuracy and consistency—e.g., at page 19 we read that "the difference between local lividity from obstruction and that from venous hyperæmia without obstruction, such as is seen in the final stages of inflammation ..... is," &c. Such a statement is scarcely on all fours with our knowledge of the vascular changes in inflammation, for it is generally conceded that the type of "hyperæmia with obstruction" is reached "in the final stages of inflammation." Nor can we subscribe to the assertion that "all active hyperæmia is always attended with pain," seeing that the physiological phenomena of blushing, and flushing of secreting glands during activity, are instances of painless fulness of the vessels. Notwithstanding these defects, which in a great measure are inseparable from a first edition, the book is one of conspicuous merit, and will be sure to meet with the support it undeniably deserves.

The text is divided into forty-four chapters. The first four treat of the general diagnosis of wounds, of injuries other than wounds, and of the constitutional effects of operations &c. Chapters V. to XIV. are occupied with an account of injuries of the chief regions of the body. Then comes a carefully detailed description of the more salient features of pulsating, fluctuating, and other swellings. Upwards of two hundred pages are devoted to the elucidation of the problems pertaining to the surgery and pathology of the more important situations, organs, and structures. We do not hesitate to say that Mr. Gould's "Elements" is unique in its excellence.

The Elements of Physiological Physics. By J. M'GREGOR-ROBERTSON, M.A., M.B., C.M., Muirhead Demonstrator of Physiology in the University of Glasgow. Cassell and Co., London, Paris, and New York.

PHYSIOLOGY cannot yet claim to be a science which is concerned solely in applying the principles of physics and chemistry to the life of the organism. Every advance in our knowledge of life tends, however, to show that ultimately this is what physiology will become; and even now it has in most of its branches advanced so far that a preliminary knowledge of these subjects is necessary in order to understand it intelligently. We have long had a distinct branch of physiology called physiological chemistry. Not so with physics; the great majority of medical students enter the physiology lecture-room without even a rudimentary knowledge of that science, and the lecturer has consequently to devote a large amount of his time to lecturing on such subjects as coils and electric currents, on the elementary principles of heat and optics, and so forth; in short, he has to lecture on physics as well as on physiology, or else he runs the risk of being unintelligible to the majority of his listeners. This difficulty will not be wholly overcome until it is a necessity for every medical student to obtain a preliminary acquaintance with physics before beginning to attend lectures on physiology. Mr. M'Gregor-Robertson's book on Physiological Physics somewhat meets this difficulty, though only to a certain extent, for the ordinary student reads as few books as he can, and the addition of a new subject to the curriculum is anything but welcome to him. With him therefore the teacher's difficulty will be as great as before. It seems to us that the book will be chiefly read by the more diligent and advanced students—those who wish to obtain a more intimate acquaintance with the details of apparatus, and with the more difficult problems in physical science on which certain parts of physiology rest.

Mr. M'Gregor-Robertson has done the student the greatest service in collecting together in a handy volume descriptions of the experiments usually performed, and of the apparatus concerned in performing them. He has also throughout the volume given directions by which the student can himself make the simpler forms of apparatus. We could have wished that more of the book had been devoted to this part of the subject, for, after all, a practical acquaintance with physiology is the most valuable kind of knowledge. This would not have much increased the size of the book; moreover, certain other parts might have been well curtailed, the relation of which to physiology is somewhat distant; we may instance the description of the various forms of barometers and thermometers.

The book, however, possesses one very serious fault; although illustrated with 218 wood engravings, the greater number of these are so small, and many so indistinct, that they are almost useless. Figures of complicated apparatus are crowded into the space of one or two square inches; the letters which mark the various objects in the figures are almost microscopic. These are referred to in the text, and the value of the description of the figures that occur there is correspondingly diminished. Mr. M'Gregor Robertson's book undoubtedly supplies a want, and if in a future edition the author sees his way to correct this error, he will still more increase its value.

Materia Medica and Therapeutics. An Introduction to the Rational Treatment of Disease. By J. MITCHELL BRUCE, M.A., M.D., F.R.C.P., Physician and Lecturer on Materia Medica at the Charing-cross Hospital. London: Cassell and Co. 1884.

THIS book, which is chiefly therapeutical in its scope, is intended as a rational guide to the student and practitioner in the treatment of disease. At the same time materia medica has not been neglected; and it has been found feasible, by the adoption of a new and entirely novel arrange-

Digitized by Google

ment, to place the chief facts in a form in which they can be quickly appreciated and readily retained. In the compass of some 550 pages the author has succeeded in giving a fairly complete abstract of the present state of our knowledge of the subjects with which he deals. The plan which he adopts of systematically tracing the physiological action and uses of the different drugs in their passage through the body, from their first contact with it locally until they are eliminated from it with the secretions, is excellent. In that part of the manual devoted to General Therapeutics a departure has been made from the ordinary arrangement by discussing the actions and uses of remedies not under the headings of Artificial Groups, but of the physiological systems of the body. The notes have evidently been compiled from trustworthy sources, and no objection can be taken to them on the score of accuracy. The section on Anæsthetics, written with the assistance of Mr. Woodhouse Braine, is especially deserving of notice. Students naturally prefer small books for examination purposes; and we have no doubt that the present work will soon become popular with them.

Surgical Handicraft. A Manual of Surgical Manipulations, Minor Surgery, and other matters connected with the Work of House-Surgeons and Surgical Dressers. By WALTER PYE, F.R.C.S., Surgeon to St. Mary's Hospital and to the Victoria Hospital for Sick Children; Examiner in Surgery in the Glasgow University. London: Henry Kimpton. 1884.

IN this work, consisting of over 500 large octavo pages, Mr. Pye describes in full detail the various surgical manipulations, dressings, and procedures that are likely to be entrusted to house surgeons. No attempt has been made to reduce the size of the book to a small compass; on the contrary, alternative plans have been described, and care has been taken to make the directions as full, detailed, and explicit as possible. Scattered through the volume are over 200 woodcuts of dressings, bandages, splints, &c., and all of them are of a high order of merit. Mr. Mills contributes an excellent chapter on the use of anæsthetics, and Mr. Field and Mr. Heyward are the respective authors of chapters on the management of aural cases and the extraction of teeth. Mr. Pye has accomplished his task with a great measure of success, and has produced a work which may be confidently recommended as thoroughly trustworthy and likely to prove very useful to those who will consult it.

THE COMMA BACILLUS.

WE have received the following "conclusions" arrived at by Dr. E. Van Ermengen after some researches upon the comma bacillus of Asiatic cholera communicated to the Microscopical Society of Belgium on October 26th. They will be seen to traverse most of the points in dispute, and to accord with Dr. Koch's results.

1. In the intestinal fluids of patients attacked with cholera (eight autopsies and thirty-four examinations of stools) there exists an organism identical with the comma bacillus discovered by Koch.

2. Its curved shaped, its S-shaped, and chain-like groups, due to juxtaposition, and its occasional formation of slightly wavy filaments, give an assemblage of microscopical characters which render it easily recognised from pathogenic microorganisms hitherto known.

3. It is more or less abundant in the choleraic products according to the period of the disease and the time of examination. In two rapidly fatal (*foudroyants*) cases it occurred in the intestinal contents almost in a pure culture. In one case of short duration, where the patient had succumbed with very marked algide phenomena, there were very few comma bacilli to be found in the intestinal fluid. They disappear from the darker stools of the reaction stage.

4. It would have been very important to search for them in the dejecta of patients attacked with so-called premonitory diarrhœa, but our investigations were not brought to bear on this point.

5. In the single case of algide cholera, where microscopic examination failed to detect numerous comma bacilli, a culture of a small quantity of the intestinal contents on soiled linen in a damp chamber yielded an incalculable number of characteristic comma bacilli in twenty-four hours.

6. Microscopical examination of dejecta can suffice to establish the diagnosis of Asiatic cholera, when preparations containing the different forms of comma bacilli in excess are obtained.

7. Bacterioscopic research supplies the deficiencies of microscopical examination in cases where the comma bacilli are scanty, and are even not found with certainty in the preparations. The characteristic aspect of their colonies, studied under a low power (150 diam.), renders them easy of recognition. The practical value of these culture processes on the glass slide in nutrient gelatine (10 per cent.) is well shown by our experiments. Mixtures of a very small quantity of the cultivation product with a considerable amount of putrefied blood, stagnant urine, fæcal matter, hay infusion, &c., yield preparations where the typical colonies of comma bacilli have been detected with readiness in the midst of most varied vegetation.

8. The study of the morphological characters of the comma bacilli at different stages of development, cultivated in various media, chiefly in chicken broth and fluid serum, shows that they should be classed with true spirilla.

9. The most varying conditions of temperature and medium have not resulted in the discovery of a stage of spore formation; and their want of resistance to drying proves that they do not produce permanent germs.

10. Gelatine cultures cease to be inoculable six or seven weeks after having been sown. Agar-agar cultures still contain living organisms after eight to nine weeks.

11. The temperature most favourable to their development seems to be that of from 25° to 37°. C. Below 16° (between 8° and 15°) they are still developed, but with difficulty.

12. Their phenomena of growth and multiplication are extremely active. In from two to three days they completely liquefy many cubic centimetres of coagulated serum.

13. The curved bacilli of the saliva, discovered by Miller (March, 1884), and believed by Dr. Lewis to be identical with the choleraic comma bacilli, do not develop in gelatine, 10 per cent.

14. The cultures of the organisms, to which MM. Finkler and Prior attribute the production of cholera nostras, are impure. That which I examined contains two kinds of bacilli. Their mode of vegetation and the appearance of their colonies in gelatine differ from those of the comma bacilli of Asiatic cholera. One of them gives to the cultivating medium a very characteristic greenish-blue fluorescence, which is wanting in the pure cultures of the comma bacilli.

15. Attempts at inoculation of the cultivation products have so far yielded very encouraging results in some species of animals, such as dogs, rabbits, and guinea-pigs. Three out of four guinea-pigs died in two or three days after the injection into the duodenum of one drop of a culture (fourth day) of the comma bacilli in liquid serum, after the method pursued by MM. Nicati and Rietsch of Marseilles. The cadaveric appearances were those of cholera, and the intestinal fluids contained large numbers of comma bacilli.

16. The pathogenic action of these products of cultivation is very likely due to a zymosis, to an unstable albuminoid compound. Corpuscles of fresh human blood placed on Ranvier's heated platinum, and brought into contact with a drop of a serum-culture, present characteristic changes wholly comparable with those described by MM. Nicati and Rietsch in their observations on the blood of choleraic cases.

17. The discovery of the comma bacillus is of the greatest importance in the diagnosis of choleriform attacks of doubtful nature which occur at the commencement of epidemics, and for the resort to more effective prophylactic measures which this early diagnosis allows.

18. The employment of bacterioscopic methods in the diagnosis of cholera does not offer any great difficulty in practice, and it would be very desirable, in view of the serious threats of an invasion of Belgium by cholera, that a sufficient number of physicians employed in the sanitary services should be initiated therein with the least possible delay.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 29, 1884.

AT a meeting of the Annual Committee of the University of London, held on the 21st inst., it was resolved, by 15 votes against 2, "That the Annual Committee recommends Convocation to again urge upon the Senate the desirability of holding the Preliminary Scientific (M.B.) Examination twice a year." At the next meeting of Convocation this will doubtless be passed as on previous occasions, and it will probably be again ignored by the Senate. The history of this question of holding the Preliminary Scientific Examination twice yearly, and so increasing the facilities for the obtaining of the medical degrees by students, is most interesting just now, when everyone is complaining of the great difficulty which the metropolitan student experiences in acquiring a degree by honest work and intelligence. On Dec. 5th, 1879, this subject was first brought to the notice of the Annual Committee, and a subcommittee was appointed to consider it. Its report was subsequently received and adopted, and at the meeting of Convocation on January 13th, 1880, it was resolved, "That the Senate be requested to consider whether it would not be desirable that in future the Preliminary Scientific and First M.B. Examinations should be held twice a year." On July 2nd, 1880, the Registrar of the University addressed a letter to the Deans of the Medical Schools, informing them that a committee of the Senate had adopted a resolution affirming the desirability of holding the Preliminary Scientific Examination twice a year, and asking for the views of the professors and teachers in the medical schools on the proposed alteration. Fifteen replies were sent to this letter, and of these thirteen were in favour of the alteration. The movement therefore had the support of the majority of the teachers in the medical schools, the Annual Committee, the graduates in Convocation, and a committee of the Senate itself. It would have been a great boon, for a student who matriculated in January was compelled to wait eighteen months before presenting himself for this examination, and a rejected student had to wait another full year, at a great expense of time and money. Everybody interested expected that the new scheme would at once come into force. But on November 19th, 1880, eleven graduates of the University and teachers of science presented a memorial to the Senate objecting to the alteration on these grounds: (1) that it would disorganise the present (or any efficient) course of study; and (2) that it would increase the difficulties of examiners, and would be likely to render it "impossible to secure the services of examiners possessing the necessary experience." A memorial of a similar tenour was addressed to the Senate on February 15th, 1881, by six graduates of the University and teachers of science. The alteration was therefore, from the first, opposed by teachers of science almost solely on grounds of personal convenience, for it is quite absurd to suppose that no alteration can be made in their courses of study. Extra work on the part of the teacher, or additional assistant for the junior students, is all that is necessary. On receipt of these memorials the report of the special committee of the Senate was referred back for reconsideration, and it was therefore deemed expedient that it should be also reconsidered by the Annual Committee and brought again before Convocation. A further subcommittee, including such representative medical teachers as the late Dr. HILTON FAGGE, Drs. BAXTER, CURNOW, and POORE, was appointed, and on April 8th, 1881, it again recommended "That the Preliminary Scientific Examination be held twice in the year," and in May, 1881, this resolution was adopted by Convocation. The opinion of Convocation and of its Annual Committee was thus fully expressed, but the Senate, acting on the advice of the science teachers and the permanent officials of the University, who of course see great difficulty in carrying out such a simple reform, declined to act on their recommendation, and adopted instead the futile suggestion of allowing a student to postpone any one subject to the year following his examination. This has now been abandoned, and new regulations have been passed by which the student is precluded from doing any medical work before passing his Preliminary Scientific Examination. No student, therefore, who wishes for the degree can enter on the scientific course and reckon any medical study which he may have previously done. The agitation for increasing the facilities by a double examination has resulted in more closely fettering the aspirant for a degree. In 1880 a letter was addressed to the Chancellor by Dr. BRISTOWE, pointing out how few of the English students became medical graduates of the University, and that this was mainly due to the severity of the matriculation and Preliminary Scientific Examination; but no heed was paid to his suggestions. In 1881 and 1882 it was moved in the Senate that "boards of studies" should be formed as a means of bringing the authorities into closer relations with the teachers, but the late Vice-Chancellor was quite indignant that such an innovation should be seriously urged, and as the "masterful" mind of Sir G. JESSEL gave but little consideration to any views which were opposed to his own, the University remains a mere examining board, out of all sympathy with teachers or pupils. This history of the Preliminary Examination, of Dr. BRISTOWE'S letter, and of the "board of studies" proposition, shows how little influence is possessed by teachers or by graduates on the deliberations and actions of the Senate, and how small a chance there is of the University adapting itself to the legitimate requirements of the medical student in the metropolis. The members of the Senate are appointed for life, and the mode of filling vacancies is so peculiar that Convocation itself can scarcely exert even an indirect influence; but to this point we must return on another occasion.

We must now enlarge the meaning of the word "hospitalism" as used by Sir JAMES SIMPSON and others. They used it with reference to the bad physical elements of the atmosphere in hospitals; and we cannot refer to this use of the word without reflecting how great and splendid have been the results of its use. They have amounted to a revolution in surgery; beginning, perhaps, three-quarters of a century ago with the improvement in the ventilation of lying-in hospitals, and ending in that almost perfect state of atmo-

Digitized by Google

sphere, compounded of fresh air *plus* disinfecting elements, in which the performance of ovariotomy in a general hospital can be made as safe as in a private and fresh house. "Hospitalism," in the sense used by Sir JAMES SIMPSON, is likely to become an obsolete word. But we need it still, and, indeed, more than ever to signify a tendency in the public to rush off to hospitals for every conceivable ailment, from a cut finger to a sore-throat. Hospitals used to be considered the refuge of the poor, now they are sought by the rich. The poor are being ousted from whole wards that those who have good beds at home may have hospital beds. The Apostle JAMES in his day administered a just rebuke to those churches which catered for people with gold rings. We want a bishop nowadays who will denounce with a prophet's indignation those hospital authorities which "sell" their wards, and congratulate themselves at the Mansion House on the success of schemes for excluding the poor from the hospitals that were built for them. This kind of hospitalism needs public attention to be directed to it, for it is proving infectious and demoralising. A hospital is meant for a class only too numerous in every large community. It can only be used for others by an entire revolution in our notions of charity. Mr. SAMPSON GAMGEE, in his recent pamphlet, raises, if he does not entirely settle, several most important questions in regard to hospitalism, in the new sense which we propose to give the word. He shows the tendency of thousands of people to flock to the hospital who never went to it before. His admirable address on "Our Medical Charities and the Working Classes," which we are glad to see published in a convenient and complete pamphlet form, contains, among many other valuable statistical tables, one giving the comparative growth of the general and the hospital population of Birmingham. We must give it entire.

	Population of Birmingham.	Patients relieved at the Birmingham medical charities.	Percentage.
1867	325,895	66,671	20·45
1876	371,839	104,048	27·98
1883	414,846	144,750	34·89

The period of sixteen years included in these dates was on the whole one in which wealth accumulated considerably in Birmingham. This should have made the people more unwilling, as it certainly made them less fit, to seek relief at hospitals. But they went to the hospital in greater numbers at the end of the period, by 14 per cent. of the population, than at the beginning. In connexion with this fact Mr. GAMGEE brings out still more prominently another—viz., that the working classes of Birmingham contribute an annually increasing sum to the hospitals. Forty years ago they gave nothing; now the expenditure of the medical charities of the town is £44,351, towards which the working classes in 1883 made the creditable contribution of £9664 8*s.*, or 21·79 per cent. Eighty per cent. of this amount is paid in three forms: annual subscriptions (£1195 4*s.* 5*d.*), registration fees (£1973 6*s.* 6*d.*), Hospital Saturday Fund (£5439 9*s.*). Birmingham is proud of its Hospital Saturday Fund, and Mr. GAMGEE is disposed to be proud of it too. We are not inclined to be severely critical in trying to find reasons for abating this pride. But if the case of Birmingham is to be taken as a model—and there is an extensive disposition to regard it so,—it is high time to inquire what is the exact value of the generosity of working men in their hospital contributions. The two facts must be taken together—viz., that the working men of Birmingham are giving more to hospitals, and that they are using hospitals more than they formerly did. At first sight this may appear right and proper. After a little examination of the facts the case is rather more doubtful. It is sometimes, and with good reason, complained that rich men use their hospital or dispensary subscription not to benefit the really poor, but to provide cheaply for the treatment of their own servants at public and charitable institutions. Is it not true that something of this kind is going on at Birmingham, and that the working classes are taking too commercial a view of their subscriptions and expecting a very big *quid* for a very small *quo?* It will be a misfortune for the Birmingham working classes to imagine that their contributions to hospitals and dispensaries entitle them to use these institutions on the ordinary medical occasions of life, or to think that they and their families are to be attended wholesale at public institutions in consideration of their contributions to the Hospital Saturday Fund or the payment of registration fees. There is another party to be considered and consulted before our hospitals can be thus commercialised—and that is the medical profession. Its members are deeply and willingly committed to the gratuitous service of hospitals and dispensaries in *fit cases.* But there is a growing determination that the cases shall be fewer and fitter, and that the Hospitals and Dispensaries themselves must take more pains to protect their staff from the exhausting and enormous demands of crowds of out-patients, half or three-fourths of whom should not appeal to the charitable principle, but be relegated to the private practitioners or the provident dispensaries of their respective neighbourhoods. We share with Mr. GAMGEE satisfaction with the disposition on the part of the working men of Birmingham to help the medical charities. We gather that he shares with us the opinion that it is necessary to guard working men from thinking that they can thus *buy* all their medical service from medical charities. We are convinced that he does from various passages in his able and important address. Hospitals and free dispensaries are for the calamities of life, and are well entitled to the benevolent subscriptions of working men. But they are not for use by well-to-do men in the ordinary medical emergencies of their life. Working men who think to use them so are deceiving themselves. They are doing not a charitable action, but one of questionable justice, not to say meanness. One striking illustration to our purpose is given by Mr. GAMGEE. The contributions of working men to the Lock and Skin Hospital in Birmingham amounted in 1883 to £574 1*s.* 5*d.*, actually £8 in excess of the expenditure. How admirable! Some politico-medical reformers would say, "Not so at all." Well over £500 of this was in registration fees. Mr. GAMGEE himself points out by implication how questionable is the application of the word "charity" to such an arrangement. What guarantee has the public—still more what guarantee has the medical profession—that the registration fees were anything but an evasion of proper medical charges for the cure of improper diseases? It will scarcely be believed by those who have not thought of the matter, that the medical profession who treated all this disease got no remuneration

Digitized by Google

for its work, and for aught that appears in Mr. GAMGEE'S address the whole system is discreditable. If care is not taken in working this system of registration fees, the medical treatment of the working classes will become more demoralising to themselves and unjust to the profession than ever. A few years ago there was a healthy and creditable discovery that the payments to club doctors were disgracefully low, and in many places they have been justly raised. But in some quarters and directions shabbiness is in the ascendant. The registration fee system is one example of this shabbiness, or may readily become such, where those who can afford to pay a medical man a pound or two a year sneak into a hospital with a registration fee. Another gross form is the Friendly Societies' Medical Institution, which, as Dr. MAUNSELL of Bath has lately powerfully shown, tries to exact a vast amount of labour from the youngest and most impecunious members of the profession for a contemptible rate of remuneration. He estimates that work which even under the old friendly society arrangements was not too liberally paid is now grossly underpaid; that what medical men got £3000 for, they get now perhaps £600. We confidently appeal to working men to denounce such injustice, and to stand by the medical men, in private or club practice, who have been amongst the best friends of themselves and their families.

DR. D. BALDI has recently undertaken a series of experiments on the process of secretion of the bile in the laboratory of M. LUCIANI of Florence, in which he has endeavoured to ascertain whether it takes place in a uniform manner in accordance with the presence or absence of food in the alimentary canal, and whether it varies materially with the nature of the food. The results are given in the third volume of the *Archives Italiennes de Biologie*. A biliary fistula was first made, the ductus communis choledochus being ligatured so that no bile entered the duodenum. Dr. BALDI found that there was a singular irregularity in the quantity of the secretion formed, distinguishing the function of the liver from all other digestive secreting organs. Not only was there great variation in the absolute quantity secreted, but the composition of the bile differed remarkably at different periods after a meal. Speaking broadly, in an animal that has been supplied with food, there is an augmentation in the total quantity of bile secreted in the course of some hours, as compared with the quantity secreted in the same time by the animal when fasting. It is not possible, however, to fix the time at which the secretion of bile after food is at its maximum; indeed, it is even possible that the maximum may be attained during some one hour when the animal is fasting. Different kinds of food, starches, proteids, fats, and mixed foods, have no appreciable effect on the quantity or quality of the bile. If we consider, in addition, that, unlike the other secretions which are poured into the intestinal tract, the bile continues to be secreted in prolonged fasting, as has been demonstrated by various experiments, we shall be led to the conclusion that this fluid, from a physiological point of view, has more analogy with urine than with the other digestive fluids. In a second series of researches, in which the effects of reputed cholagogue drugs were investigated, Dr. BALDI is not in accord with either RÖHRIG or with RUTHERFORD. RÖHRIG found that colocynth was the most active cholagogue; then, in succession, jalap, aloes, senna, and rhubarb. RUTHERFORD considered the order to be—podophyllin, rhubarb, aloes, colocynth, senna, and other drugs. BALDI experimented with podophyllin, rhubarb, jalap, sodium phosphate, pilocarpine, and Carlsbad water, and, from his results, feels inclined to doubt altogether the cholagogue value of all these substances. He admits, however, that the presence of a biliary fistula seriously interferes with the action of remedies. Dr. BALDI undertook still another series of experiments, to determine whether bile injected into the blood was excreted by the liver. The animal employed was the dog. The bile injected was that of the ox deprived of mucus. Dog bile is brown; ox bile green. Almost immediately after the injection of ox bile the colour of the bile secreted by the dog became green.

MR. FLEET has lost his case against the Metropolitan Asylums Board in connexion with the small-pox encampment at Darenth. His contention was that the camp constituted a danger of infection to his house, which stood at a distance of 655 yards from the nearest portion of the site that was used by patients. This point, and the question as to whether the Asylums Board had done anything illegal in their provision and management of the camp, were the only matters that came before the High Court of Justice. Mr. Justice PEARSON, in giving judgment, expressed his gratification that the issue was thus limited, adding that he had feared he might have had to decide upon the great dispute as to the aerial dissemination of the small-pox contagium. On the general question, Mr. Justice PEARSON pointed out that any experience with respect to London small-pox hospitals, situated as they are in a densely peopled city, could not of itself be held to apply to the camp of Darenth, which had been placed in a sparsely populated locality. In London, he admitted that the evidence went to show that small-pox did spread in the immediate vicinity of hospitals, but at Darenth there was an absence of any such evidence, and hence he could not but conclude that the plaintiff had failed to prove his case. He, however, gave the plaintiff a very strong hint as to the lines on which his action should have been based by saying that he "could hardly think anything more destructive of the amenities of a residential property than the neighbourhood of a small-pox hospital, nor did he understand the defendants to say that no injury was done to the property as a place of residence."

From a scientific point of view the trial has been a disappointing one. It has already been abundantly proved that under the conditions of a large town an aggregation of acute small-pox patients beyond a very limited number does constitute a source of danger to the community. But at Darenth the circumstances are different; for setting aside a period of extreme pressure, when small-pox patients in all stages were sent to Darenth, the camp has been reserved for convalescents and mild cases. These circumstances are entirely new, and no attempt was made to deal with them. If the plaintiff had maintained that mild cases were really acute ones, although in an early stage of the disease, and that hence aerial diffusion was as likely to result at Darenth as in London, some interesting evidence might have been forthcoming, notwithstanding the fact that owing to the

Digitized by Google

sparse population there was as yet hardly any one to be affected at Darenth. But as the case now stands, it is evident that in the opinion of Mr. Justice PEARSON, town small-pox hospitals, if resembling in their circumstances what the London ones have heretofore been, can properly be closed as a danger to public health; whereas, on the other hand, the burden of proof that injury has already resulted will lie with the plaintiff in the case of hospitals in localities having rural characteristics. As regards the Metropolitan Asylums Board, we are bound to acknowledge the unceasing energy which they have displayed in their efforts to provide for the isolation of metropolitan small-pox cases, and we can only hope that this mingling of acute cases—under the name of mild cases—with convalescents, in the large numbers which their Darenth camp is capable of containing, will not eventually constitute a new element of danger.

Annotations.

"Ne quid nimis."

APOTHECARIES' SOCIETY: EXAMINATION IN SURGERY.

THE Court of Assistants of the Apothecaries' Society have resolved to institute an examination in surgery for those candidates for the L.S.A. who have not already passed an examination in Surgery at one of the Royal Colleges, or at one of the universities, or such other examining body as may be deemed satisfactory to the Court of Examiners. The examination in Surgery will be held twice a week, and will consist of written questions, clinical diagnosis and treatment, and the uses of instruments. It will be necessary for candidates holding no surgical qualification to pass this examination before admission for the ordinary examination, which may be done immediately after passing the surgical examination.

SIR LYON PLAYFAIR ON MEDICAL LEGISLATION.

SIR LYON PLAYFAIR has been saying his usual list of pleasant things to the universities and medical corporations of Scotland, in the hope of securing his re-election for the university. He speaks with the air of a man who can shape the future Medical Bill, conscious no doubt of having wrecked the Bill of last year. We can believe anything of Parliament and parties at present except a capacity for sound and honest work, and we see no improbability in the idea that Sir Lyon Playfair's wisdom will be accepted by the present Parliament in place of the wisdom of a Royal Commission and the immense majority of the medical profession. This infallible guide, who told the House of Commons that our much over-stocked profession was disappearing at the rate of 1600 a year, and that there was a risk of the public not being sufficiently supplied with medical men, told his constituents that a Bill of three clauses would meet all the necessities of the case, and that he hoped to see such a Bill next session. The three points to be secured are: sufficient examination in Medicine, Surgery, and Midwifery; a properly representative Medical Council; and, thirdly, that the Council should inquire and report upon, and if necessary render more efficient, the modes of teaching and examination of the different bodies which give medical education and licences. Our readers will observe that this programme contains no guarantee of any reduction in the twenty competing bodies, throws on the profession the cost of maintaining them, and on the Council the impossible duty of checking and supervising them all. Verily, the exigencies of a candidate for an election are terrible, and he has to bid high for the favours of his constituents. To judge from Sir Lyon Playfair's address one would fancy that the Scotch medical authorities, including the Corporations, had raised the profession to its present eminence, and that no evidence was forthcoming to show that the said corporations had sold fellowships, made thousands of pounds by the sale of licences, and given diplomas with freedom to men rejected by other boards. All we can say is that if Parliament can be so misled by Sir Lyon Playfair, so much the worse for Parliament. We shall certainly be no parties to treating so slightly the deep wounds of an "agitated" and misrepresented profession.

"MORBID RELIGIOUS AFFECTION."

WE have nothing to add to and nothing to withdraw from our remarks on this subject, in spite of letters approving and letters condemning the position we have taken up. It may be granted at once that it is to be regretted that there should be any need to refer to topics of such a class and character; but evil must not be allowed to work because it requires some courage to deal with it. We have not spoken precipitately, or made rash statements. It is necessary to be cruel to be kind, when those who are in a dream of folly have to be awakened. We say again that religious affection is too often morbid. In the interests of true and sober-minded religion it is essential to expose that which is simply emotional and has evil tendencies. It is not, confessedly, our business to pose as critics of honesty in conviction. The medical standpoint is, however, one which not only enables but compels the practitioner of physic to include in his field of vision much of the mental and moral life of his patient. When we see morbid religious affection paving the way for disease it is our duty to speak out plainly; and let us take leave to say that we are not to be deterred from the discharge of what we believe to be our duty by any imputation of falseness, wantonness, or wickedness. We believe, and cannot therefore hesitate to say, that the ecstatic reverie of worship or adoration into which women are wont to throw themselves before the crucifix *is* "vicious" and demoralising. We do not say that they are conscious of the real nature of the emotional excitement stirred within them; but this does not affect the fact that it is an undesirable—most undesirable—state, and we must reiterate the expression of a hope that heads of families and ministers of religion, who think more of the intellectual integrity and the mental and physical health of their people than of forms and ceremonies and "ways and means of grace," will interpose to put a stop to practices in religion which tend to undermine the very health and happiness they are designed to advance and improve. Anything and everything that suspends the control of the will, even for a moment, is injurious. Ecstasy and reverie are, physiologically considered, states of mental unsoundness. It is idle to speak of sullying the mind and moral purity by warning those who are forming the habit of falling into these states against that tendency, because the very existence of a state of ecstasy or reverie implies and involves surrender of the mind to all contingencies. It is as difficult for a woman abandoning herself to this ecstasy to prevent her thoughts from drifting into impure channels as it would be for a man entering upon a drunken tirade to determine that he would be coherent and reasonable. The "emotional nature" is as nearly allied to the passions as these latter are to the organs of which they are the function. The mischief that results from thinking and speaking of the "mind" as something apart from the body, as more than brain-function, cannot be over-estimated.

Digitized by Google

It is the cause of most of the troubles and difficulties we have to encounter in striving to live natural and healthy lives. There is peril, grave besetting peril, in the tolerance of mind-states which do not fall under the direct, active, and continuous control of the will. Waking dreams are madness while they last, and the sort of day dream which grows out of the contemplation of the crucifix is one that may readily become morbid, and in so doing deprave the moral sense—first, because the state is mentally unsound, and, second, because the object of contemplation has special elements which may readily suggest impure thoughts.

DISEASED MEAT.

A FEW days since the Tiverton magistrates had before them an important case for decision. It was one in which the question was raised as to the fitness of a carcase of beef for human food. The facts, which were briefly as follows, were not disputed. A dairyman named Hellyer owned a cow which had recently calved. As the animal was suffering from "milk fever" Mr. Chase, the veterinary surgeon to the sanitary authority, was asked to give his advice in the matter; this he did to the effect that the animal should be slaughtered, and inasmuch as the flesh presented a healthy appearance he saw no reason why it should be destroyed. The butcher, with commendable straightforwardness, informed the sanitary inspector that the carcase was in his possession, and requested him to take what course he thought fit. Dr. J. P. McNeil, medical officer of health, stated to the Court that he considered the flesh of a diseased cow, especially after the birth of a calf, as unwholesome food, admitting at the same time that he was not in a position to condemn it on the grounds of any morbid appearances. The magistrates, after inspecting the four quarters, held that they did not see their way to condemn the meat, especially as the veterinary surgeon "could not see how the flesh could be diseased." The question, What is diseased meat? is an exceedingly difficult one to answer satisfactorily. It is needless to say that the flesh of animals infested with parasites should be discarded, seeing how uncertain are the methods of rendering the peccant bodies inert. Nor do we hesitate to affirm that animal matter which has undergone rapid putrefaction should be unreservedly condemned. The unfortunate results of eating rotten meat hitherto experienced are sufficient justifications of this assertion; but there still remains a group of cases, amongst which are included those of animals dead of specific or infective fevers, about which opinions differ as regards the propriety of allowing the carcases to be used as human food. That the latter must have deteriorated from the action of living organisms and the concomitant conditions of the febrile state is beyond dispute; but this in itself falls short of the proposition that such meat is absolutely dangerous as an article of diet. Nevertheless, we maintain that since it has been proved that certain specific diseases are communicable from animals to man, and that the flesh of animals affected with the acute fevers is very prone to decompose with the formation of what may be deadly cadaveric principles (whether these consist of fatty derivatives, microbes, or alkaloidal ptomaines matters little), we hold that the balance of evidence is in favour of prohibiting the sale or consumption of meat which at any rate contains the elements of danger, if not a certain cause of poisoning. This would undoubtedly entail a serious pecuniary loss on those immediately concerned, and would be felt in the aggregate by the community at large, though of course to a less degree; but the objection to such a procedure falls to the ground in the face of the greater one that health, and even life, may be sacrificed on terms which no reasonable being would willingly accept. It seems a little puzzling to reconcile the advice of Mr. Chase, that the cow should be killed to save it from impending death by disease, with his statement that the carcase might be eaten with safety, and that he would not hesitate to partake of it himself. However, if a person chooses to run a blockade he cannot complain if his ship is disabled or sunk, but it is quite another matter to recommend, or even sanction, the enterprise by one ignorant of the risks attending it. Possibly on the whole the most practicable plan of dealing with the matter of meat "under a cloud" would be to judge each case on its merits, providing that the opinion of the medical officer of health be paramount.

THE BISHOP OF PETERBOROUGH AND SIR ANDREW CLARK ON TEMPERANCE.

THE cause of true temperance is in the ascendant, and will be greatly helped by such speeches as that of the Bishop of Peterborough and Sir Andrew Clark. It is greatly to the credit of the Bishop that he has sided with the Church Temperance Society, and so far done what he could to counteract the influence of that little smart epigram into which he fell a few years ago, and which, though in senses true, was in its main application highly questionable. The teetotalers will put themselves entirely in the wrong if they do not meet the Bishop half way, and endeavour to make common cause with all who try to increase the sobriety and abate the drunkenness of the nation. Absolute abstention is a moral necessity for those who cannot observe moderation, and a medical necessity for a large number of cases of alcoholism. What we want is "earnest advocates" of "temperance" in the sense of the great Apostle who "reasoned" about it, men who can admit, like Sir Andrew Clark, that while "not necessary for health," there are many persons to whom it has not yet been proved that certain small quantities of alcohol, taken at stated times, at dinner and supper, are injurious. Let us abolish casual drinking, tippling, public-house drinking, and careless social uses of alcohol. This will cut off nine-tenths of the disease which now desolates families and disgraces British Christianity.

ACUTE RHEUMATIC ARTERITIS (?).

A CASE which possessed considerable interest and not a little rarity was narrated by M. Legroux at a recent meeting of the Société Médicale des Hôpitaux. The patient was a young lady, aged twenty-two, whose family history was only characterised by the presence of the arthritic diathesis. In July, 1884, she had a second attack of acute rheumatism; a first having occurred at the age of twelve years, but had left no trace behind it. The rheumatism was of a subacute character; some joints became painful, rose coloured, and a little swollen, but during the moderate fever an eruption of nodose erythema appeared on the front surface of both legs. After the lapse of three weeks the patient went to the seaside and seemed to improve considerably. At the beginning of August there was quotidian fever, which could only be explained on the assumption of a malarial origin. On the 15th of August there suddenly appeared numbness of the left hand, forearm, and arm, soon followed by acute pains and inability to move the fingers or other parts of the limb. When seen by a doctor after these new symptoms, the radial, ulnar, and brachial pulse could not be felt on the left side; the limb was icy cold; the hand and forearm were a little swollen, and presented on their dorsal aspect some spots of a rose-brown colour. Gangrene was feared, but did not occur. The fever, although somewhat abated by the administration of sulphate of quinine, still continued, and after the fresh incident increased once more; the pulse numbered 110 to 120 a minute; the temperature reached 38° to 39° C., and soon precordial pain, dyspnœa, palpitation, and a murmur of systolic time masked a pre-existing hæmic bruit

Digitized by Google

The murmur was loudest at the apex beat, but extended towards the base and all over the aortic area. The first diagnosis made by the patient's ordinary attendant was ulcerative endocarditis with embolic thrombosis of the left brachial artery. There was a little tenderness about the left brachial artery. Dr. Charles Hardy, who saw the patient later, suggested that acute rheumatic inflammation of the artery existed because of the nodosities to be felt along the vessel, of the sensitiveness of the vessel, and of the presence of a bruit all along the thoracic aorta. The obliteration would on this opinion have been due to the acute arteritis, possibly starting from the endocardium and aorta. The limb was kept absolutely at rest, the pains were calmed by hypodermic injections of morphia, and small doses of iodide of potassium were administered. Some time after M. Legroux saw the patient for the first time. The cardiac disturbance was then marked by loud bruits, and the action of the heart was so tumultuous that it was almost impossible to differentiate the various factors of this commotion. There was an intense bruit all down the vertebral column corresponding to the path of the aorta; auscultation over the left subclavian region yielded a loud bruit. There was a tender pulsatile dilatation of the axillary artery of the size of a large plum. Below the aneurysm the brachial artery was to be felt as a hard, fibrous, pulseless cord. The limb was pale, flabby, wasted, and motionless; the hand was atrophied, and a deep furrow in front of the lunule of the nails indicated the period at which the circulation had been almost completely arrested. A small degree of sensibility remained. A slight effusion into the right pleural cavity was diagnosed. The ultimate issue of the case is not yet known.

INVALID HOTELS.

THE project of establishing hotels for the reception of invalids in London is one which, if planned with due consideration and carefully carried out, ought to command the support of the class for whom it is intended. The idea is not a new one; it is the extended, but also modified and trained, development of that which has been known as the "home-hospital" system. We may say that it differs essentially from the latter in the predominance of the home element over the hospital. Comfort is provided for as at the large general hotels, but with special regard for the necessities of disease, while at the same time exclusive centralisation, that fruitful source of quack practice, would seem to be in a great measure obviated. The prospectus which lies before us disclaims any purpose of organising a hotel medical staff, or portion of a staff. The invalid tenant is to be attended by any practitioner whom he may choose; he has his separate room, receives, subject to medical restriction, the visits of his friends, and has access under all ordinary conditions to such society as his state allows. He is in fact a sick man in chambers, where he can be cared for. In one part of the plan, the employment of a trained nursing staff under the control of matrons, the hospital principle is introduced unchanged. A compromise is thus designed between the methods of private medical practice on the one hand and those of the nursing home on the other. The blend might be a happy one or it might not. The proposed measure, it seems to us, though better than others which have preceded it, still has its weak point in this dissimilar association. Decentralisation goes hardly far enough, not so far as the title of the new establishment suggests that it will do, and not so far but that the hope of harmonious action between medical men and their nursing assistants must chiefly, if not wholly, depend upon the even balance of their social qualities. This is committing too much to human nature. The experience of Guy's Hospital a year or two ago has weakened our belief in nursing corporations. It would probably be more satisfactory to all concerned if nurses and doctors alike were available for hotel patients on some system approximately similar to that which now exists in family practice. By maintaining a fixed moderate scale of remuneration and a code of board regulations where necessary, this result, we think, might conveniently be achieved. We have spoken of the hotel principle as an extension of that of the pay hospital or home hospital. It is so inasmuch as it is intended to meet the requirements of no one class, but of all save the poorest classes, which, as hitherto, we still consider to be the appropriate charge of those great and free charities, the hospitals in the original and truest sense. The invalid hotel of whatever grade, and this no doubt may vary, should be, in short, the resort of strangers, of sick strangers, a place where they can feel at home and can be treated and healed as if they were at home. Its institution, if it be maintained as we have suggested, so that puff, quackery, and caucus over-pressure shall be equally condemned in it, need not disturb the fair equilibrium of medical work, while it will afford to many in their sickness a relief from avoidable anxiety.

DIPHTHERIA IN MICHIGAN.

THE recently published annual report of the State Board of Health for Michigan contains a number of very interesting papers. Amongst the subjects dealt with a somewhat prominent position is given to diphtheria, a special committee having been appointed for the purpose of investigating it, and a list of questions having been prepared by Drs. Kellogg and Avery, and issued to a large number of medical men. Briefly stated, the conclusions at which the committee arrive are as follows:—The disease is due to the invasion of the system by a microscopic fungus, the growth of the bacteria resulting in fibrinous infiltration and inflammation, with invasion of the blood and the whole system, the patient by his breath, &c., throwing off great quantities of the infecting material. The contagiousness of the disease is regarded as unquestionable. The contagion is looked upon as capable of attaching itself to articles of clothing, &c., and of being communicable to some of the lower animals. The poison may be retained for months, and perhaps for years, but either drying or putrefaction rapidly destroys its activity. Amongst the predisposing influences, the age of from one to five years is stated to be that during which susceptibility is at its greatest, and acute catarrh of the throat and bad sanitary surroundings are mentioned as favouring the reception of the infection. With regard to the relation of diphtheria to other diseases, all that can be said is that there appears to be some sort of relation between it and true croup, scarlet fever, and some other septic diseases. Dr. Baker, the secretary to the board, also contributes a paper on the distribution of deaths from diphtheria in the State.

MEDICAL STUDENTS AND ROWDYISM.

A SCENE of disorder seldom occurs in London without being attributed to medical students. This we think is very unjust to a class of men who are as a rule certainly young and, as befits the arduous profession they have adopted, robust and full of health and its concomitant high spirits. We venture to assert that if Charles Dickens were writing now he would have some difficulty in finding in our hospitals Bob Sawyers and Allens to typify the medical student. The medical student of the present day may be, as we have said, full of health and spirits, but he is not a rowdy or a rough; and it is unfair that he should have to bear the opprobrium and reproaches heaped on the head of such. On Monday evening last a disgraceful disturbance occurred at Covent Garden Theatre, at the close of the Promenade Concerts. It is stated to have arisen out of "an organised plan by a gang of *so-called* (the italics are our own) 'medical students' and

Digitized by Google

others." We are glad to note and emphasise the qualification in this instance. It is true that certain cries were raised, such as "Guy's to the front!" and "Medicals to the rescue!" and it is probable that there was some medical student element in the crowd. Nevertheless we do not believe that this turbulent and discreditable scene was planned in our hospitals, or carried out by their students. Four persons were subsequently accused at Bow-street Police-court of complicity in these disorders, three of them being fined—not by any means too severely—and the fourth ordered to find a surety in £20 for his good behaviour for a month. It is significant to note that of these one was described as a builder, another as a merchant, and a third as a gentleman, the occupation of the last, who was identified as one of those who shouted "Guy's to the rescue!" not being given; he, however, denied that he knew any medical students, and excused his conduct on the ground of over-indulgence in drink.

NEPHRECTOMY FOR CALCULOUS PYELITIS.

THE dependence of the issue of nephrectomy upon the healthy state of functional activity of the remaining organ is adverted to by Dr. E. Sonnenburg, who details a fatal case in which the non-extirpated kidney exhibited no definite structural change. The case (*Berliner Klinische Wochenschrift*, Nov. 24th) was that of a woman fifty-two years of age, who had suffered from pain in the right loin since last Easter, accompanied by fever, wasting, and polyuria. She came under Dr. Sonnenburg's care in August, when the presence of a large fluctuating tumour in the right half of the abdomen was ascertained, and on aspiration pus was drawn off from it. Nephrectomy by the abdominal incision was performed on August 25th. The operation was difficult and tedious, the thin wall of the cyst rupturing in the removal. The whole pedicle was secured to the wound, but it was found impossible to suture the peritoneum. The organ was converted into a chambered, pus-containing sac, with numerous thin-walled outlying cysts, and a large branching calculus was lodged in the dilated pelvis. Hardly any renal tissue remained. Great collapse followed, terminating in death on the second day, and during the whole interval no urine at all was secreted. There was no peritonitis; the left kidney weighed 190 grammes, and was anæmic, but histologically almost normal, except for some localised fatty degeneration of the renal cells and slight increase in places of the interstitial tissue. The fatal issue of the case could not, Dr. Sonnenburg thinks, be attributed to the shock of the operation and the collapse alone; but that the condition of anuria, the cause of which remains unexplained, was in the main answerable for this result.

OPENING OF THE PARIS SCHOOLS.

THE Medical Session in Paris begins in November, and our enterprising contemporary *Le Progrès Médical* always devotes some space to a description of the introductory lectures of the various professors, which may be mentioned briefly here. M. Falret commenced a course of lectures on Mental Diseases at the Salpêtrière by dealing with the subject of classification and showing its imperfections, and proposing to treat in his course with what are termed the new forms of insanity. M. Lannelongue, discoursing on Surgical Pathology, avowed himself a follower of Lister and a believer in the germ theory. M. Blanchard treats of the subject of "Medical Natural History," and commenced his course of lectures by drawing attention to the close affinities, physiological and pathological, between man and the anthropoid apes. M. Trélat opened his course of Clinical Surgery at the Charité Hospital by some general remarks upon clinica teaching, and the method he intended to pursue. At the Morgue Professor Brouardel was presented with an address from the students, testifying to the regard in which he is held and their appreciation of his efforts to utilise for instruction in legal medicine the rich material of that institution. M. Sée began his lectures on Clinical Medicine at the Hôtel Dieu by insisting on the necessity of combining its study with physiology, histology and pathological anatomy, and instanced the light thrown upon clinical medicine by micro-biology—e.g, in tuberculosis, pneumonia, and cholera. He then discussed some of the symptoms of cardiac disease, and the value of convallaria as a diuretic and regulator of the heart's action. At the Salpêtrière M. Charcot's clinic was, as usual, most numerously attended. He took for his subject the disease which was first described by himself, amyotrophic lateral sclerosis, illustrated it by the exhibition of a well-marked case, and pointed out that cases occur, as in tabes, of an incomplete or abortive kind. M. Charcot's lectures are delivered on Fridays. M. Duplay lectured at the Faculty on Operative Medicine—in other words, surgical therapeutics; he devoted his first lecture to a study of the general conditions of the patient, external and internal, which govern operative procedure. M. Magnan began his course of Mental Pathology, discriminating between two great classes of mental diseases:—(1) Mixed states belonging to general pathology and psychiatry, as general paralysis, senile dementia (cerebral atheroma); circumscribed lesions (softenings, hæmorrhages, tumours, &c.); hysteria, epilepsy; intoxications (alcohol, absinthe, morphia, opium, &c.) (2) Insanity or psychosis, including chronic delirium, intermittent insanity, insanity of the degenerate, mania, and melancholia. M. Le Fort, in commencing his course of Clinical Surgery at the Necker Hospital, spoke on the germ theory; M. Strauss dealt with cholera in beginning his lectures on Pathological Anatomy. M. Cornil, who holds daily demonstrations at the Hôtel Dieu, began his weekly lectures on the 12th, with a description of the comma bacillus and its culture. Lectures on Diseases of Children were commenced by M. Legroux at the Faculty of Medicine, and by M. Joffroy, who has succeeded the late M. Parrot at the hospital.

THE DRAINAGE OF PRIVATE HOUSES.

THE near approach of cholera has once more awakened public attention to the necessity of drainage improvements. The newspaper-reading community are called upon to "put their houses in order," and the assurance is given that then the cholera need not be feared. This advice, however, is far easier to give than to carry out. A great number of tenants in London and in many other large towns hold their houses on merely a three years' lease. It is not to be expected that they should incur any considerable expense for improvements which at the end of the short lease would enable the landlord to augment his rent and oust his tenants. On the other hand, the landlord almost invariably refuses to make the required improvements; nor do the sanitary authorities move in the matter unless the nuisance be of a very flagrant description. Most tenants, too, are very chary of complaining to the sanitary authorities; not a few are in arrears with their rent, or at least irregular in the payment, and under such circumstances are anxious to avoid anything that may lead to unpleasantness. Finally, there is no fixed official standard as to what constitutes a well-drained house. In this respect the sanitary administration of Brussels is better organised than anything we possess on this side of the Channel. At the Hôtel de Ville of Brussels may be seen specifications given by the Service d'Hygiène of what the law imposes. If any lodger, tenant, or other person have reason to suppose that in any particular house the principles laid down by these specifications are not carried out, he has only to report the fact. An official inspection is at once made. If the landlord inquires from

Digitized by Google

what source the complaint emanated, he is politely informed that that has nothing to do with the question. Either his house is in order, and if so there could be no objection to the fact being confirmed by the official inspector of the town; or the drainage is not in a proper condition, and of course it would be only right that he should conform to the general regulations. Thus it is well known what should be done, who should do it, and how that person may be compelled to act, without the tenants or others being involved in any unpleasantness.

OXFORD GRADUATES' MEDICAL CLUB.

THE second dinner of this Club was held at Limmer's Hotel on Thursday, November 20th, and, as members were allowed to introduce guests belonging to their own or the sister university, a large assemblage took place, which was presided over by Sir H. Acland. The objects of the Club are the maintenance of associations with the University and the promotion of good-fellowship among the members. In fulfilment of this many came from the country to attend this meeting, amongst others Professor Burdon Sanderson, Mr. Pridgin Teale, Dr. Griffin, &c., whilst London was represented by a large number of well-known physicians and surgeons. The health of the Club, which was proposed from the chair, was responded to by Dr. Fincham, the President, who paid a warm tribute to the secretaries, Dr. Samuel West and Mr. John H. Morgan, whose exertions had been attended by such satisfactory results, as was shown by the numbers of the Club, which already amounted to upwards of ninety, and for which several fresh candidates had sought admission since the inaugural dinner in June last. He in turn proposed the health of the Cambridge Medical Graduates' Club, coupling with the toast the name of Professor Humphry, which was most enthusiastically received. Dr. Humphry made a very eloquent speech, and alluded to the interests and sympathies which both universities possessed in common, and, touching with much tact and delicacy upon the various parts which each had taken in furthering medical education, pointed out that while differing in their views on this subject each had much to learn from the other. The health of the chairman was proposed by Dr. Andrew, and after this had been responded to the members spent the remainder of a very enjoyable evening in renewing acquaintanceships and in discussing the many medical topics in which Oxford men are now taking so prominent a part.

AN ANALYSIS OF CASES OF DIPHTHERIA.

AT a recent meeting of the Berlin Medical Society Dr. Henoch read a paper upon diphtheria, as observed in the Charité Hospital in the years 1882 and 1883, the full text of which is to be published in the next "Charité-Annalen." Exclusive of doubtful cases of angina, so-called scarlatinal diphtheria, and idiopathic croup, no fewer than 319 cases of the disease were observed; 216 of these were between the ages of two and six years. The mortality was very high—viz., 208,—particularly in the first three years of life, for only 17 out of 118 attacked in this period recovered. This high mortality was ascribed partly to the "genius epidemicus," partly to the insanitary surroundings of the sick, and to the fact that many of them were tuberculous and of the lowest class. In 145 cases the larynx was implicated, and 129 of these succumbed; of the remaining 174 cases, 79 died. Tracheotomy was performed in 138 cases, with only 16 recoveries—i.e., 11½ per cent.; but 17 of these deaths were due to the supervention of scarlet fever. Of 66 cases tracheotomised in the first three years of life only 2 survived; death being almost invariably due to croupous bronchitis or broncho-pneumonia; but occasionally to erysipelas of the wound and diphtheritic collapse. On an average the greatest danger to life was from the second to the fourth day after the operation. Speaking of the associated conditions and symptoms, Dr. Henoch said that, scarlatinal cases excluded, cutaneous eruptions were rare. In three cases a diffuse urticarial-like erythema was noted over the nates and extensor surfaces of the extremities. Swelling of the submaxillary glands was constantly observed; but except in highly malignant cases it did not pass on to suppuration. In no case—except one doubtful scarlatinal one—was there swelling of joints; nor endocarditis, which was never found post mortem. Albuminuria was most common, and if it reached an amount of about one-third or more was regarded as of bad prognostic significance; for in such a case it indicated either intense blood-poisoning or nephritis, which *per se* was an element of danger even after the diphtheria had passed away. Dropsy, however, rarely occurred, and uræmic symptoms were never observed. This nephritis, which could hardly be considered a true sequel, was frequently associated with cardiac debility, the occurrence of inflammations, and diphtherial paralyses. The use of corrosive sublimate as a gargle, of arsenic and iron, and of papayotin in serious cases, was advocated.

THE HEREDITY OF LONGEVITY.

IT would be interesting to study more closely, in the case of centenarians and other aged people, the ages of their near relatives and immediate ancestors. It will probably be found not rarely that long-lived persons have not been stronger than those who have been short-lived. They have their "often-infirmities" like other people. It will also frequently be found that their brothers and sisters have been as short-lived, or more so, than others. At the same time an element of heredity may not seldom be traced, or may have to be recognised, for we have not yet sufficient data for dogmatic conclusions. We are able to give to-day some few more particulars of the ages of the immediate family relatives of Sir Moses Montefiore, which we have reason to believe are correct, though in one particular at variance with a statement in a previous number. Thus one parent died at seventy-nine, one at eighty-three, his grandfather at eighty-seven, his grandmother at ninety-three, a brother at seventy-five, another at sixty-nine, a sister at eighty-four, another at seventy-nine, another at eighty-two. These nine ages at death give an average longevity of eighty-one years. The first four—those of the parents and grandparents of Sir Moses—give an average of eighty-five years.

THORBURN v. CRAWFORD.

THIS action, which, in our opinion, ought never to have been brought, was tried last week by Mr. Justice Manisty and a special jury. The plaintiff, Dr. Thorburn, lately a Surgeon-Major in the Army, sued the present Director-General of the Medical Department for an alleged libel contained in a letter written by him in 1882, when he was Surgeon-General and Principal Medical Officer in Bengal. The case, as stated by Dr. Thorburn's counsel, was that in 1881 the stewards of the races at Delhi had suspended Dr. Thorburn from "riding, training, and running horses on the course," in consequence of a charge brought against him of having ordered a pony of his to be "pulled" on purpose to lose the race. On an appeal to the stewards of the Calcutta Turf Club this decision was confirmed. The result of this appeal was published in the Calcutta papers and thus became matter of public notoriety. Dr. Crawford felt it his duty, in the interests of the discipline, good conduct, and repute of the department of which he was the responsible head, to bring the circumstances to the notice of the Commander-in-Chief in India, who ordered a Court of Inquiry

Digitized by Google

to be held. Dr. Thorburn had in the meantime sent in an application to retire from the service, receiving a gratuity. He subsequently wished to withdraw this, but was refused permission by the military authorities. Dr. Thorburn brought the present action against Dr. Crawford, alleging that as a result of his letter "he had been injured in his reputation and had been compelled to retire from the service," and claiming £10,000 as damages for the injury thus done him. Dr. Crawford pleaded "privilege, denying that he wrote maliciously or that in consequence of his letter the plaintiff was injured or compelled to retire." Dr. Thorburn's counsel, Mr. C. Russell, Q.C., stated the case for the plaintiff, but admitted that Dr. Crawford had "only discharged his duty in sending the letter, and that he would have failed in his duty if he had not sent it"; and he also admitted that an officer under such circumstances was not liable to any action. The learned counsel stated that the action was brought by Dr. Thorburn to vindicate his character and to have an opportunity of denying the charges against him. We think this hardly justifies the course adopted of bringing an action against an officer who clearly had only discharged his duty. According even to his counsel's statement, Dr. Thorburn appears to have been remiss in taking steps to have the charges judicially investigated at the proper time. "In this, no doubt, he committed a mistake in not demanding a court-martial," we presume when they were first brought against him. On the application of Mr. Russell a juror was withdrawn, and the case thus dropped without any verdict. It has been from first to last a most unpleasant affair, and while we cannot help feeling sorry for the plaintiff, we also feel that Dr. Crawford has been exposed to an amount of unjustifiable annoyance and worry for having simply done his duty. Surely some less objectionable way might have been found to afford the plaintiff an opportunity of making public a denial of the charges which had been brought against him in India.

DR. BALTHAZAR FOSTER AS A CANDIDATE FOR PARLIAMENT.

WE see with great satisfaction that Dr. Balthazar Foster of Birmingham is to be a candidate, in the Liberal interest, for Chester. We wish him every success. Of course we have no politics in the vulgar sense of that word; but we wish to advance the best interests of the people, and we see no better way of doing this than by sending some of our best men to Parliament, where their large human experience and enlightened professional knowledge will be likely to tell. We should expect, too, that Dr. Foster, if he were in Parliament, would mercilessly expose those refined forms of obstruction to medical legislation which have discredited some would-be representatives of the profession, and brought them into very questionable Parliamentary company.

CRUELTY TO ANIMALS.

IT is satisfactory to find that in these days, thanks to the existence of a Royal Society for the Prevention of Cruelty to Animals and to the fact of our having sensible and humane judges on the Bench, animals cannot *always* be ill-treated with impunity. An appeal against a decision of the magistrates of Petworth, in Sussex, in a case in which a man named Gilham was prosecuted by the above Society for having contravened the Wild Birds Protection Act of 1880 under the following circumstances, was heard in the Court of Queen's Bench recently. He had trapped a large number of sparrows on March 15th, and sent them in bags, each containing six dozen, to the Swan Hotel, Pulborough, the manager of which bought them for 1*s.* 6*d.* a dozen, for the purpose of a starling and sparrow shooting match which was held in the grounds on the 17th. The birds were placed under flower-pots, which were made to serve as traps, and many of them were in so exhausted a state from being kept so long in the bags that they would not rise, on which they were either pulled or kicked to death. The magistrates dismissed the charge on the ground that proof had not been given by the prosecution that Gilham had not the licence or authority of the occupier of the land on which the birds were netted. This decision was reversed by Mr. Justice Hawkins and Mr. Justice Grove, the former adding: "This case will be sent back to the magistrates to convict, and I hope when they do convict they will pass an exemplary sentence on all who took part in the brutal sport of shooting at these wretched birds." All trap-shooting is cruel, but in this particular case cruelty seems to have followed cruelty in a very shocking way. We trust, therefore, that the magistrates, even if themselves supporters of pigeon-shooting from traps, may be deterred by no scruples from following Mr. Justice Hawkins's advice. The same Society was also successful at Manchester the other day in a charge they brought against a horse-slaughterer for disposing of a horse for hard work that had been left at his yard for the purpose of slaughter, contrary to the provision of the Act 13 and 14 Vict., sec. 9. We were glad, too, to see that a man described as a porter has been deservedly sentenced to a month's hard labour for what the magistrate described as "most arrant brutality" to a cat. We take this opportunity of reminding those who are responsible for the state of our streets that a free, and above all a prompt, use of sand when the wooden paving is slippery from frost or greasy from slight rain may be the saving of much cruelty to horses.

TESTIMONIAL TO DR. HANDFIELD JONES.

WE understand that the retirement of Dr. Handfield Jones from the post of senior physician to St. Mary's Hospital, an institution with which he has been connected for over thirty years, will be made the occasion for presenting him with a testimonial by his colleagues, pupils, and friends. No man has done more to advance the cause of scientific medicine than Dr. Handfield Jones, and we do not doubt that his valuable labours will meet with a fitting recognition. The subscription to the fund is limited to one guinea, which should be sent to either of the honorary secretaries. Malcolm Morris, Esq., 63, Montagu-square; or A. J. Pepper, Esq., 122, Gower-street, W.C.

DISINFECTING STOVES.

A NUMBER of new contrivances for the disinfection of infected bedding, clothing, and other articles by heat have recently appeared, and sanitary authorities seem somewhat in difficulty as to their efficiency. Any stove or other apparatus professing effectually to disinfect by heat should be capable of securing a uniform temperature throughout all parts of the disinfecting chamber of not less than 250° Fahrenheit, and this temperature should be capable of thoroughly penetrating such articles as bedding, &c. In this country there are not many appliances which can be trusted to produce this result, both uniformity of temperature and power of penetration often failing. Dr. Ransom's stove, as manufactured by Messrs. Goddard and Massey of Nottingham, is one which after long experience may be trusted in these respects, and it has the immense advantage over others that, owing to the automatic contrivance which controls the amount of gas which is consumed in producing the heat, it needs but little supervision, and it ensures the greatest procurable economy by the fact that no more gas is consumed than is required to maintain the heat at which the regulator is set. Mr. Washington Lyon's steam disinfector stands foremost amongst disinfecting chambers where steam under pressure is relied on. It, too, has

Digitized by Google

certain special advantages. In the first place, its power of penetration is much more rapid than in the case of stoves in which dry air is used, and hence it has largely come into use in towns where a large amount of disinfection has to be carried out; it is, in short, certain and quick in its action, and can hardly be excelled. When compared with the Ransom stove, it has the drawback that the use of steam involves constant skilled attendance; but, on the other hand, steam can be used in places where gas is not available. These two disinfecting chambers are, in our opinion, by far the best yet manufactured, and they may be fully trusted to secure the end desired. Amongst the others which have been manufactured, we may, however, mention a steam apparatus which has recently been made by Messrs. Benham. We have reason to believe that it also is efficient for all ordinary purposes, but as yet it has hardly been put to the test of experience to which the others have been subjected. Failing a really efficient apparatus which responds to the conditions we have laid down, sanitary authorities would do well to rely on effectual fumigation of articles that can be spread out, and the destruction of others.

PARTIAL INQUESTS.

WHETHER from respect for the feelings of common jurymen or from a want of due appreciation of the duties attaching to their official position we know not, but this much is certain, many of our coroners fail to carry out the provisions of the law, which enacts that an inquiry shall be held as to "when, where, and *by what means*" So-and-so came by his or her death. We have repeatedly called attention to the unsatisfactory way in which inquests are too frequently conducted, or rather concluded, and quite recently our attention has been directed to the same point. On Monday, Nov. 17th, an inquiry was held at Waingroves touching the death of Lydia Shawcroft, aged sixty-six. The deceased was seen alive and apparently well at 8.45 A.M. on Saturday; at 4.30 in the afternoon she was found dead on the floor, the body being quite cold. The jury, "at the suggestion of the coroner," returned a verdict of "Death from natural causes." It does not appear in the report that a post-mortem examination was made, nor even that medical evidence was taken. We ask the question, Was all reasonable care taken to show that death was not the result of accident or other mode of violence? Unless the answer can be given in the affirmative, and we fail to see the grounds for it, it is clear the verdict was not wholly warranted by the evidence. In a second case investigated at Manchester on Nov. 29th, the cause of death of a woman, aged forty-one, was the subject of inquiry. It appears that the deceased, who suffered from bronchitis, took some "Balsam cough elixir." Shortly afterwards she felt sleepy; this was followed by coma and death. The coroner advised the jury that inasmuch as persons poisoned by morphia or opium—it was not proved that the "elixir" contained either—usually fell into a stupor some time before death, and that in the present instance the fatal issue quickly supervened, it did not seem probable that death was due to opium poisoning. He then left it to their discretion whether an analysis of the elixir should be made, and very naturally they were content with the matter as it then stood, and forthwith brought in their verdict of "Death from natural causes, probably bronchitis or heart disease." Now, whether the administration of the patent medicine had any part in causing the death—and this was the main point at issue—was left unsolved, and the object of the inquiry remained as problematical as ever. If there be an instance in which it is important to decide the exact share that each of several possible factors has taken in bringing about the death of a person, it is one like that under consideration, for there is no other mishap from which the public stand in need of warning and protection more than that arising from ignorance of the properties of drugs vaunted as specifics, and sold without the expressed or implied information that danger is to be apprehended from small doses in diseased states, or large ones in healthy. We take exception to the view of the coroner respecting the action of a narcotic in a patient suffering from acute bronchitis.

ASIATIC CHOLERA IN NORTH AMERICA.

AN important conference was held at St. Louis last month on the threatened extension of Asiatic cholera to the North American continent, and on the action necessary to prevent or limit a cholera epidemic. Dr. Rauch, Secretary to the Illinois State Board of Health, contributed a paper dealing with the practical recommendations necessary to secure the desired end; this was followed by one by Surgeon Smart, U.S.A., on "Quarantine, and the Sanitary Methods formulated by the National Board of Health," which went to show that the principles advocated by that Board very much resemble those in practice in this country, and that cleanliness, medical inspection, and isolation are the essential remedies; and then Dr. Chancellor followed by asking "Can epidemic diseases be excluded by sanitary cordons?" Dr. Chancellor is inclined to some views which we hardly concur in, but these in no way interfere with the value of his conclusions that quarantine cannot be trusted to prevent the importation of cholera, and that it is on an enlightened sanitary control of towns and cities, and on such measures as cleanliness &c., that people must in the main rely. Dr. Baker (Michigan) was the reporter of a special committee appointed by the Conference, and he, with the concurrence of his fellow-workers, reported that three factors were essential to the prevalence of cholera on the American continent: first, the importation of the disease by means of ships, more or less directly from its only place of origin in India; second, local insanitary conditions favourable to the reception and development of the disease; and, third, persons sick with the disease in some of its stages, or things infected by such sick persons, to carry it from place to place. The recommendations as to action, whether by the State, sanitary bodies, or individuals, were based on the acceptance of these three factors, and, with the exception of the representatives from Minnesota, who refrained from voting because they thought the paper was too important to be dealt with without further consideration, the Conference was unanimous in accepting the conclusions formulated.

DENTAL ANÆSTHETICS.

THE two deaths that have lately occurred in dental practice show but too clearly the necessity there is of some definite opinion on the subject. Nitrous oxide gas has so long held the pride of place in dental anæsthesia that in London it is very seldom any other anæsthetic is ever required, and when the request for such is made it is because the patient has had some experience (generally of chloroform), or it is a matter of economy and convenience in which the operating dentist acquiesces, if he has not already insisted upon it. The difficulties attending upon the exhibition of nitrous oxide in the provinces are, however, often so prohibitory that we are constantly startled with the announcement of a death from some other anæsthetic agent; and this is more easily understood when it is known that the simplest gas apparatus requires almost constant use for its efficiency, and thorough practice in its manipulation on the part of the administrator, if nitrous oxide is to be exhibited deftly. Should there be any operation of sufficient magnitude about the mouth, that it cannot be performed under three or four administrations of nitrous oxide gas, it ought

Digitized by Google

to be treated, as far as the anæsthetic is concerned, with just as much dignity as any other surgical operation. The latest American dental chairs are least suitable of any for such work for many reasons. A high sofa or surgical operating table, with the patient duly prepared and placed in a horizontal position, ought to be the preliminaries in experienced hands; the choice of anæsthetic that in which the administrator has a constant experience. The subsequent administration of ether to a preliminary exhibition of nitrous oxide gas robs the latter of its good name and best qualities.

UNQUALIFIED ASSISTANTS AND THE MEDICAL ACT.

UNQUALIFIED assistants and those who employ them should take warning from a case at Hammersmith the other day, in which an unqualified assistant was fined in the maximum penalty of £20, and ordered to pay 23*s.* costs, recoverable by distress. The complainant was John Tomlin, and the defendant Henry Trist. The complainant alleged that he was led to think the defendant a properly qualified practitioner by seeing premises with "Surgery" written up, a notice that a medical man attended daily, and finding the defendant in the consulting-room, who examined him and prescribed for him. The complainant was much dissatisfied with the treatment, and called in Mr. Cooney, under whose care he got well. It does not appear from the report before us that the defendant called himself a medical man or by a medical title, but that he put himself falsely in the position of a medical practitioner. His solicitor tried to get him off on the theory that he was the assistant of a medical man, Mr. Lintoff, and that it was the practice to employ unqualified assistants, who, he said, were preferred to those who have diplomas! We commend this defence to the Licensing Bodies. We regret to notice that the report adds that Mr. Cooney, on leaving the Court, was assaulted, though the complainant said in his evidence that he had not taken the proceedings on the recommendation of Mr. Cooney. The case is only one of many showing that the law will not shelter either unqualified assistants or those who employ them to act independently.

THE PONTIFICAL HOSPITAL.

IN view of the return of cholera to Italy, the Pope is, at his own expense, constructing a hospital on a considerable scale. It will stand near the little church of Santa Maria on the Vatican Hill, almost within the shadow of St. Peter's. Its drainage will be carried to the Tiber by a great conduit now half completed. Its area, quite isolated, will occupy 69,000 square metres, and its water-supply every twenty-four hours will amount to 120 cubic metres for drinking and 1000 cubic metres for other purposes. The building will comprise seven blocks, with three spacious gardens besides the courtyards. The hospital itself will stand in the centre, and will consist of four storeys in addition to the ground-floor, the latter containing the residence and bureau of the medical superintendent, the telephone office, the reception room for patients, the lift, the *ruota* or revolving machine for receiving provisions from without, the dispensary and pharmacy, the kitchen and refectory, the gasometer, the baths and the boiler for disinfecting the linen conveyed to it by an iron tube which opens on each floor. To the east of the grounds are the laundry and the apparatus for the dry-air disinfection of wearing apparel; to the north the *corps de garde*. There are, besides, ante-chambers for the examination of the dead, with electric arrangements for each bed, a mortuary and pathological room, with a furnace for the combustion of refuse; there are, further, a steam-generator for the different services, magazines for funeral-cars, fire engines, ice machines, and such like apparatus. The infirmary proper on the upper floors of the hospital will have every means of maintaining cleanliness, disinfection, and the isolation (when necessary) of the sick. Ample accommodation is also being provided for the confessors, the sisters of charity or nurses, the resident physicians and pharmacists; while a separate house or tents will be organised for convalescents. The entire arrangements have been planned under the direction of Dr. Ceccarelli, surgeon to his Holiness, with the assistance of the architect, Signor Mannucci, and of the engineer, Signor Gismondi, and, when in full working order, the hospital with its adjacent temple will form a nineteenth century reproduction of the old Æsclepian system under which the care and cure of body and soul were made ancillary to each other.

KING HUMBERT.

KING HUMBERT of Italy is one of the most fortunate of sovereigns. He stands high in the esteem of his people, and deservedly so. The Roman citizens on his entry into the capital thronged the streets, we are told, regardless of the wintry weather, and filled the air with the sound of a welcome deeper and more cordial than that of mere State courtesy. They were giving voice to their feeling of respect for one who, being critically placed, knew how to rally and lead them and their fellow-subjects in adversity. It cannot be said of them that they only praised the King, but rather that the free and disinterested devotion shown by him in his practical sympathy with a sister city has proved to their heart and judgment that a King is at his best when he is most a man among men.

VACCINATION AGAINST YELLOW FEVER.

THE researches which have during the past two years been made by Dr. Domingos Freire have now reached a new point of departure. This investigator has prepared an attenuated virus with which he proposes to vaccinate individuals, with a view to rendering them proof against the occurrence of yellow fever. The Emperor of Brazil, having regard to the alleged innocuousness of the prepared virus, has authorised the practice of vaccination. Dr. Freire has accordingly vaccinated five hundred individuals. Three captains and all the crews of English vessels have been vaccinated with a view of escaping the infection from yellow fever, which prevails at Rio Janeiro. Thus far none of the vaccinated people have been attacked by the disease, and none of them suffered the least inconvenience from the operation. M. Bouley, who gave the facts to the Académie de Médecine, whilst implicitly believing the above-narrated facts, does not yet implicitly accept the views of Dr. Freire on the micrococcus xanthogenicus.

HÆMOGLOBINURIA AND SYPHILIS.

THE pathogeny of intermittent or paroxysmal hæmoglobinuria is shrouded in obscurity. The notion that it is related to malarial disease is now almost abandoned, at any rate as a universal proposition. Its dependence upon exposure to cold led to the hypothesis that it was due to vascular engorgement of the kidney, and that in that organ the blood-cells were broken up and the hæmoglobin excreted. Such a theory may be called the vaso-motor hypothesis, but it cannot be invoked in many cases. Others have suggested that the corpuscular disintegration was due to the absorption of bile acids into the blood, or to some less manifest change in the fluid. That the syphilitic poison is sometimes a factor, as some allege, is supported in a few cases mainly by the effects of treatment. In the *Berliner Klinisch. Wochenschrift* for the 10th inst. is recorded a case by Herr Gotze, from Professor Rossbach's clinic, where a child of nine years, the subject of inherited syphilis, became liable to the

Digitized by Google

affection on the slightest exposure to cold or even slight changes in temperature. A resort to iodide of potassium, and to mercurial inunctions, was followed by a freedom from liability to the attacks which could but be regarded as a cure; for even immersion in ice-cold water of the extremities, and once of the whole body, failed to reproduce the hæmoglobinuria after this course of treatment.

IRISH UNIVERSITY REPRESENTATION.

MR. GLADSTONE never speaks of the medical profession but with respect and apparently sincere desire to advance its dignity and its unity. In a recent utterance he expressed his wish to see it more largely represented in Parliament, though not seeing how medical men could be admitted into Parliament save through the ordinary methods of popular election. Dr. Augustus H. Bampton, in *The Times*, expresses a hope that the claims of the graduates of the Royal University of Ireland will not be overlooked in the new Bill. We quite share this hope. This University has absorbed the graduates of the late Queen's University, a large proportion of whom are medical graduates. A member for the new University would be an act of justice at once to the University and to the profession.

PORRO'S OPERATION AND LAPAROTOMY FOR ILEUS.

La Gazzetta degli Ospitali of November 19th reports that Dr. Vincenzo Lesi performed Porro's operation in the civil hospital of Imola on the 23rd ult. The patient was rachitic, and had been in labour many hours. Ten days after the operation, absence of fever and other favourable conditions justified hope in complete recovery. Laparotomy for ileus, with fæcal vomiting of ten days' duration, was performed at Florence by Dr. Edgard Kurz on the 2nd inst. The strangulated portion of intestine was readily found and liberated, the operation being completed in half an hour, under the spray and with iodoform dressing. Soon afterwards free action of the bowels commenced; the patient took liquid nourishment with appetite, and recovery proceeded rapidly, without febrile or other disturbance.

EXCISION OF TUMOUR FROM THE BRAIN.

ON Tuesday last, at the Hospital for Epilepsy and Paralysis, Regent's-park, a tumour was successfully removed from the substance of the brain. The case is under the care of Dr. Hughes Bennett, who, having diagnosed an encephalic morbid growth of limited size, and localised it in the upper part of the fissure of Rolando, requested a surgeon to trephine the skull over the suspected region. This was carried out by Mr. Rickman Godlee. A mass of glioma the size of a walnut was extracted from under the grey matter of the upper part of the ascending frontal convolution. Up to the present time the patient has progressed favourably in every respect. We shall be glad to learn the future progress of the case.

SUCCESSFUL REMOVAL OF THE LARYNX.

MR. JORDAN LLOYD last Saturday removed the larynx from a man, aged fifty-one, who was progressing favourably on Wednesday, with every prospect of a successful issue. We shall give a report of the operation and sequel in a future number.

THE COMBINATION SCHEME.

WE publish at page 972 the series of regulations relating to the professional education and examinations in connexion with the Combined Scheme of the Royal College of Physicians and the Royal College of Surgeons.

FROM the report on the composition and quality of daily samples of the water supplied to London during the month of October, recently issued by Messrs. Crookes, Odling, and Tidy, it appears that of the 188 samples subjected to examination 3 were found to be very slightly turbid; the remaining 185 being perfectly clear, bright, and well filtered. As regards degree of freedom from organic matter, the water more than maintained the character it has now exhibited continuously for a long time past. Thus, while the mean proportion of organic carbon in the water supplied by the Thames Companies during the previous three months was ·128 part in 100,000 parts, the mean proportion in that supplied during the past month was only ·118 part in 100,000 parts, corresponding to about two-tenths of a grain of organic matter per gallon; this excessively low proportion of organic matter being quite unusual for the period of the year.

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several Metropolitan water companies during the month of October, it appears that the Thames water was of practically the same quality as in the previous month, the proportion of organic matter being again small, as in all the samples collected since March last. The water drawn from the Lea also exhibited no material change, the amount of organic matter in it being less than in the samples of Thames water. All the waters were clear and bright on delivery.

DR. MURRAY LINDSAY, superintendent physician of the Derbyshire Lunatic Asylum at Mickleover, was on the 25th inst. severely wounded while entering one of the wards of that institution. One of the patients had been lying in wait for him, and succeeded in inflicting three stabs upon him with a chisel before being overpowered. Although the wounds are severe, one under the fifth rib, the second in the groin, and the third on the hip, it is expected that Dr. Lindsay will recover.

ON Wednesday, the 19th inst., the works for the amelioration of the Roman Campagna were commenced. Two hundred labourers have pitched their tents in the ravine of the Almo, a tiny affluent of the Tiber, between the Via Appia Antica and the Via Appia Nuova, and are employed on the desiccation of the soil. At night their encampment is picturesquely illuminated with bonfires of dead leaves and brambles with which they seek to disinfect the air.

DRS. FINKLER and PRIOR have replied to Dr. Koch's strictures on their recent methods of research on bacilli in simple cholera by a letter to the *Kölnische Zeitung*. For thus appealing to the public in a lay journal rather than to the profession through the medical press they have been severely blamed, especially as the *Zeitung* had not previously published Dr. Koch's criticism.

THE members of the medical profession in Paris strongly oppose the admission of female medical students to the hospital wards. It is stated that not one French lady student has applied for admission, all the candidates being Russians, Roumanians, and Americans.

DR. T. W. MILLS has been appointed Professor of Physiology and General Pathology in McGill Medical College, in the room of Professor Osler, who has been elected to the chair of Clinical Medicine in the University of Pennsylvania.

THE epidemic of measles at Aberdeen seems to be spreading with alarming rapidity among the children in the city. The infant departments of the public schools and most of the Sunday schools have been closed.

EXAMINING BOARD IN ENGLAND, BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND,

Under the Provisions of Clause XIX. of the Medical Act (1858).

REGULATIONS RELATING TO PROFESSIONAL EDUCATION AND EXAMINATIONS.

SECTION I.

Professional Education.—Any candidate who desires to obtain both the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to comply with the following regulations, and to pass the examinations hereinafter set forth. (See Section II.) Every such candidate who shall commence professional study on or after October 1st, 1884, will be required, at the times prescribed in Section II. for the respective examinations, to produce satisfactory evidence:—

1. Of having been registered as a medical student by the General Medical Council. (See regulations of the General Medical Council, to be obtained of the Registrar, 299, Oxford-street, London, W. Note A.—Professional studies commenced before registration, except in the cases of chemistry and chemical physics, materia medica, botany, and pharmacy, will not be recognized.

2. Of having been engaged in professional studies at least forty-five months, during which not less than three winter sessions and two summer sessions shall have been passed at one or more of the medical schools recognised by the two Colleges. One winter session and two summer sessions may be passed in one or more of the following ways:—(*a*) Attending the practice of a hospital, infirmary, or other institution, recognised as affording satisfactory opportunities for professional study; (*b*) Receiving instruction as a pupil of a legally qualified practitioner holding such a public appointment, or having such opportunities of imparting a practical knowledge of medicine, surgery, or midwifery, as shall be satisfactory to the two Colleges. (*c*) Attending lectures on one or more of the required subjects of professional study at a recognised place of instruction.

3. Of having received instruction in the following subjects:—(*a*) Chemistry, including chemical physics, meaning thereby heat, light, and electricity. (*b*) Practical chemistry. (*c*) Materia medica; (*d*) Botany. (*e*) Pharmacy. Note B: The instruction in practical pharmacy must be given by a registered medical practitioner, or by a member of the Pharmaceutical Society of Great Britain, or in a public hospital, infirmary, or dispensary.

4. Of having performed dissections, at a recognised medical school, during not less than twelve months.

5. Of having attended, at a recognised medical school:—(*a*) A course of lectures on anatomy during not less than six months, or one winter session. (*b*) A course of lectures on general anatomy and physiology during not less than six months, or one winter session. (*c*) A separate practical course of general anatomy and physiology during not less than three months.

6. Of having attended, at a recognised medical school:—(*a*) A course of lectures on medicine during not less than six months, or one winter session. (*b*) A course of lectures on surgery during not less than six months, or one winter session. (*c*) A course of lectures on midwifery and diseases peculiar to women during not less than three months. Note C: A certificate must also be produced of attendance on not less than twenty labours, which certificate must be signed by one or more legally qualified practitioners. (*d*) Systematic practical instruction in medicine, surgery, and midwifery, including—(1) the application of anatomical knowledge to the investigation of disease; (2) the methods of examining various organs and other parts of the body, in order to detect the evidence of disease or the effects of accidents; (3) the employment of instruments and apparatus used in diagnosis or treatment; (4) the examination of diseased structures, whether recent or in a museum; (5) the chemical examination of morbid products; (6) the performance of operations on the dead body; (7) post-mortem examinations. (*e*) A course of lectures on pathological anatomy during not less than three months. (*f*) Demonstrations in the post-mortem room during the whole period of attendance on clinical lectures. (See Clause 8.) (*g*) A course of lectures on forensic medicine during not less than three months.

7. Of having attended, at a recognised hospital or hospitals, the practice of medicine and surgery during three winter and two summer sessions. Note D: No metropolitan hospital is recognised which contains less than 150, and no provincial or colonial hospital which contains less than 100 patients. A three months' course of clinical instruction in the wards of a recognised lunatic hospital or asylum may be submitted for the same period of attendance in the medical wards of a general hospital.

8. Of having attended, at a recognised hospital or hospitals, during nine months clinical lectures on medicine, and during nine months clinical lectures on surgery, and of having been engaged during a period of three months in the clinical study of diseases peculiar to women. Note E: These clinical lectures must be attended after the candidate has passed the second examination.

9. Of having discharged, after he has passed the second examination, the duties of a medical clinical clerk during six months, and of a surgical dresser during other six months. Note F.—These duties may be discharged at a general hospital, infirmary, or dispensary, or parochial or union infirmary, recognised for this purpose, or in such other similar manner as shall, in the opinion of the two Colleges, afford sufficient opportunity for the acquirement of practical knowledge.

10. Of having received instruction in the practice of vaccination. Note G: The certificate must be such as will qualify its holder to contract as a public vaccinator under the regulations, at the time in force, of the Local Government Board. Students are required to attend examinations which are held in the several classes. N.B.—Exemption from any of the foregoing regulations can only be granted by the committee of management.

SECTION II.

Professional Examinations.—There are three professional examinations, called herein the first examination, the second examination, and the third or final examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. N.B.—Every candidate intending to present himself for examination is required to give notice in writing to the registrar of the Royal College of Physicians, or to the secretary of the Royal College of Surgeons, fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates. All fees must be paid three days prior to the day on which the examination commences.

The First Examination.—The subjects of the first examination are: Chemistry and chemical physics, meaning thereby heat, light, and electricity. Materia medica, medical botany, and pharmacy. Elementary anatomy, and elementary physiology. (Synopses indicating the range of subjects in the examinations in chemistry and chemical physics, materia medica, medical botany, pharmacy, elementary anatomy, and elementary physiology may be obtained, together with the regulations.) A candidate may take this examination in two parts at different times, or he may present himself for the whole at one time. A candidate will be admitted to the examination on chemistry and chemical physics, materia medica, medical botany, and pharmacy on producing evidence of having been registered as a medical student by the General Medical Council, and of having complied with the regulations prescribed in Section I., Clause 3; but he will not be admitted to the examination on elementary anatomy and elementary physiology earlier than the end of his first winter session at a medical school. A candidate rejected in either part or in both parts of the first examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. The fees for admission to the first examination are as follows:—For the whole examination, £10 10s.; for re-examination after rejection in either of the two parts, £3 3s. Any candidate who shall produce satisfactory evidence of having passed an examination on any of the subjects of the first part of this examination conducted at a University in the United Kingdom, in India, or in a British Colony, will be exempt from examination on those subjects in which he has passed.

The Second Examination.—The subjects of the second examination are:—Anatomy, physiology. (A synopsis indicating the range of subjects in the examination in physiology may be obtained with the regulations.) A candidate may present himself for examination in either of these subjects or parts separately, or in both at one time. A candidate will be admitted to the second examination after the lapse of not less than six months from the date of his passing the first examination, on producing evidence of having completed, subsequently to registration as a medical student, eighteen months of professional study at a recognised medical school or schools, and of having complied with the regulations prescribed in Section I., Clauses 4 and 5. A candidate rejected in either part or in both parts of the second examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be re-examined in the subject or subjects in which he has been rejected. The fees for admission to the second examination are as follow:—For the whole examination, £10 10s.; for re-examination after rejection in either of the two parts, £3 3s.

The Third or Final Examination.—The subjects of the final examination are:—Medicine, including therapeutics, medical anatomy, and pathology; surgery, including surgical anatomy and pathology; midwifery, and diseases peculiar to women. (Questions on forensic medicine and public health will be included in the third or final examination.) A candidate may present himself for examination in these three subjects or parts separately or at one time. A candidate will be admitted to the third or final examination on producing evidence:—1. Of being twenty-one years of age. 2. Of having passed the second examination. 3. Of having studied medicine, surgery, and midwifery, in accordance with the regulations prescribed in Section I., Clauses 2 and 6 to 10. The Colleges do not admit to either part of the Third or final examination any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least forty-five months, nor till the expiration of two years after his having passed the second examination.—NOTE: Students are recommended to pass these two years in acquiring practical knowledge in the wards, or in the out-patients' department, of a recognised hospital. A candidate rejected in the third or final examination, or in one or more of the three parts into which he may have divided it, will not be admitted to re-examination until after the lapse of a period of not less than six months from the

Digitized by Google

date of rejection, and he will be re-examined in the subject or subjects in which he previously failed to pass. Any candidate who shall have obtained a colonial, Indian, or foreign qualification which entitles him to practise medicine or surgery in the country where such qualification has been conferred, after a course of study and an examination equivalent to those required by the regulations of the two Colleges, shall, on production of satisfactory evidence as to age, and proficiency in vaccination, be admissible to the second and third examinations. The fees for admission to the third or final examination are as follows:—For the whole examination, £15 15s.; for re-examination after rejection in medicine, £5 5s.; for re-examination after rejection in surgery, £5 5s.; for re-examination after rejection in midwifery, £3 3s. Every candidate who shall have passed the third or final examination is, subject to the bye-laws of the two Colleges, entitled to receive the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England. (Forms of the required certificates may be obtained of the registrar of the Royal College of Physicians, or of the secretary of the Royal College of Surgeons.)

FREDERICK A. MAHOMED, M.B. CANTAB., F.R.C.P. LOND.

ANOTHER instance of a fellow-labourer of great promise

"Dead, dead ere his prime."

The profession in London for the last fortnight had been aware that this brave worker in the fever-field was himself smitten with typhoid and had trembled for the result, which, alas! is very bad. We shall not now attempt to do justice to the labours and to the hopes of Mahomed, for he was a bold and ambitious explorer "in the regions beyond" the accepted limits of pathology. It is not the least significant proof of his character that we are supplied or premised on all hands, from worthy contemporaries, not to say rivals, accounts of his work and of himself. One, and no mean tribute, from a capable and generous hand we here produce:—

"I have known Frederick Mahomed during the whole period of his too short career in scientific medicine, and he has always seemed to have possessed an individuality far more strongly marked than most of us who are his contemporaries. It must be twelve years ago that there appeared in the *Medical Times* that series of papers upon the sphygmograph which at once stamped him as an ardent and industrious student; indeed, he was characterised by an ardour and energy which often made him formulate propositions far in advance of the ideas of his more cautious comrades, and led him sometimes into mistaken inferences, but none the less honestly believed and advocated. It was a common saying that no one but Mahomed could interpret all the teachings of the sphygmograph, and it may be that this study of its records led him to place too strong a reliance upon the faithfulness of a mechanical contrivance, without due allowance for its necessary imperfections. In spite of that it cannot be denied that his fervent advocacy did much to re-establish the sphygmograph in clinical estimation. These early studies of the pulse gave a bias to all his future work, which was mainly centred upon the subject of Bright's disease. One of the first fruits of this pursuit is to be found in the paper read in 1874 before the Royal Medical and Chirurgical Society on the Pre-albuminuric Stage of Scarlatinal Nephritis. He showed here from a wide experience, due to his connexion with the London Fever Hospital, that the occurrence of albuminuria in scarlatinal subjects was preceded by increase in arterial tension, and often by the transudation into the urine of hæmoglobin; and he showed, further, that this was so constantly preceded by constipation as to suggest a causative relation, and the prescription of purgation with the view of anticipating, and even preventing, the supervention of nephritis. The importance of such an increase in arterial tension as a prodromal phenomenon in renal disease became clearer to him as time went on; and he devoted himself to solve the riddle of Bright's disease, and determine the significance of albuminuria. His last production on this subject is to be found in the recently issued volume of Guy's Hospital Reports, but he had previously made it the subject of his graduation thesis at Cambridge University, and communicated a paper upon it to the International Medical Congress of 1881, as well as to a previous volume of the Reports. It is beyond my power to condense into a few words the outcome of all this labour, for his writings upon the subject teem with pathological and clinical observations. Suffice it to say that the attempt to lay greater stress upon cardio-vascular change than upon the structural lesions of the kidney was supported by many facts, and harmonised with the doctrine of arterio-capillary fibrosis expounded by Sir W. Gull and Dr. Sutton. But Mahomed did not confine himself to this one subject, vast as that subject was. His activities and sympathies were far wider. He was a most constant attendant at the meetings of the metropolitan medical societies, and a frequent speaker in the discussions, showing a familiarity with many subjects and the good use to which he had put his faculty of observation and his retentive memory. Of late his activity seemed to have redoubled, and as an instance may be cited the fact that last spring he attended a meeting of the Glasgow Pathological and Clinical Society to take part in a debate on albuminuria, while at the same time he contributed the results of his experience of the use of cold baths in the treatment of typhoid fever to the Medical Society of London. It may here be remarked that his experience of this treatment at the London Fever Hospital convinced him of its utility to such an extent that he urged its adoption in his own case, but owing to the mild course of the fever in its early weeks it was not deemed necessary to resort to it. The work with which Mahomed himself would perhaps most wish to be remembered is, I imagine, not his personal scientific labour so much as the share he took in establishing a scheme to encourage accurate observation and record by medical practitioners generally. Whatever may be the outcome of collective investigation, and to what extent it will be found practically useful, it is almost entirely owing to him that the idea took form in this country, in the British Medical Association. The movement has since been taken up by other countries, and finally by the International Medical Congress. All who have been associated with him in the furtherance of this scheme must have felt how largely the whole plan and method of procedure were the creation of himself; and such progress as collective investigation has made in this country is mainly due to the unremitting labour and enthusiastic advocacy which he bestowed on it. To those who have held aloof from the movement, or who see in it no practical gain, we would wish for a little of this enthusiastic spirit. It must not be forgotten that as yet and for some time to come the prosecution of the work must be regarded as experimental. No one—not even the sanguine mind of Mahomed himself—could have imagined that so novel and striking an effort should be commenced in as perfect a form as it was possible it might attain; but the central principle of the movement remains unshaken, no matter how faulty the methods whereby it is carried on. It is an extension of the same idea and the endeavour to collate facts bearing on the transmission and affinities of diseases that has been attempted by Mr. Francis Galton, in conjunction with Dr. Mahomed, in the encouragement of family registers; and the anthropometrical laboratory, so popular at the Health Exhibition, was a type of an institution which the same inquirers hoped might one day be multiplied over the country. It was upon these collateral subjects, which some may regard as impracticable, that Mahomed expended much time and energy, pursuing them with what to many seemed an almost Quixotic ardour. Yet on these subjects, as on others, he did not rest until he had followed them up to the full; and everything he undertook, down to his last public act at the College of Physicians, where he vainly urged the College to take measures to enforce the regulation of the sale of drugs, was done with an intensity and a fervour rarely to be met with. It was by virtue of these qualities that, young as he was, Frederick Mahomed was perhaps better and more widely known than any of his contemporaries; and in the knowledge of these elements in his character his friends felt that there was opening to him a prosperous career—now, alas! abruptly brought to a close."

The first symptoms of Dr. Mahomed's fatal illness appeared on October 30th, the day on which he brought forward at the Royal College of Physicians a motion to appoint a committee for the purpose of urging the Government to exercise control over the quality and composition of patent medicines and drugs. Then followed some days of malaise, and in about a week the true nature of the malady became clear. For the first fortnight the fever ran a mild course, being marked by constipation. Then the temperature rose to 104°, and on the nineteenth day a severe attack of intes-

Digitized by Google

tinal hæmorrhage created considerable anxiety. The recurrence of hæmorrhage and the supervention of extreme tympanites increased the state of exhaustion under which he sank in the early morning of the 22nd inst. During his illness he was attended by Drs. Cayley, Broadbent, and Wilks.

THE PROGRESS OF CHOLERA.

CHOLERA still continues to decline in Paris, and on the alleged ground that the epidemic has subsided no further bulletins are to be issued. We very much doubt the expediency of this step, especially as during the twenty-four hours preceding its announcement nineteen cholera deaths took place in the city. The desire may be to remove needless alarm, and to intimate to intending visitors that there is no further reason why they should stay away from Paris; but, coming as the intimation does at the termination of a period of seven days during which 203 deaths occurred from the very disease which is regarded as having disappeared as an epidemic, the proceeding is certainly liable to be interpreted as an indication to hush up the mortality that still takes place, and we fear it may have a contrary effect to that which is anticipated. Even after the disease has altogether disappeared people may feel disinclined to believe it, when they remember that nineteen deaths a day were not deemed worthy of being announced. Elsewhere in France the disease may for the present be regarded as having subsided.

From Spain comes definite information as to a not inconsiderable number of cases and deaths at Toledo (around which town a sanitary cordon has been established) and at Beniope, both of them places from which deaths had previously been announced. The absence, however, of any material spread of the disease in Spain is a hopeful sign.

Foreign consuls are now, it is stated, giving clean bills of health to vessels from Naples.

THE METROPOLITAN ASYLUMS BOARD.

AT the usual meeting of this Board on the 22nd inst., the chairman congratulated the managers upon the result of the action which was recently brought against them by Mr. Fleet of Darenth in regard to the small-pox camp, and upon the proof which the trial afforded that the camp had been conducted with judgment and care. In the report of the North-Western Hospital (Hampstead) committee, Dr. Gayton, medical officer of that asylum, gave some examples of "how small-pox is spread" outside the walls of asylums. The first case mentioned was that of a man who, feeling ill, went to St. Bartholomew's Hospital on Nov. 7th, and after sitting in the waiting-room for some time was seen by a medical man. He was told that he would be admitted, and then went home to tell his wife. He returned to the hospital, was placed in a room through which about one hundred persons passed while he was there, and was put, after being bathed in the usual way, in a ward in which there were other persons. The next day he was seen by a physician, and pronounced to be suffering from small-pox. The patient was ordered to be removed at once, and came to the asylum at Hampstead, dressed in his ordinary clothes. The man was suffering so acutely that he died nine hours and a half after admission. The next case was that of a chemist's assistant, who spent four hours in the House of Commons, presumably in the Strangers' Gallery, after suffering from the initiatory fever of small-pox. The next day, when the eruption had appeared, he served in his employer's shop, and continued to do so until he was taken to the hospital. A third case was that of a young woman who lived in the caretaker's rooms of a school at Hampstead. When suffering from the premonitory symptoms on Nov. 10th, she rode to London in an omnibus to see the Lord Mayor's Show, and mingled with the crowd; she afterwards rode to Regent-street in an omnibus. It was resolved, with respect to the first-mentioned case, that the authorities of St. Bartholomew's Hospital should have their attention drawn to the statements made by the patient, and some members remarked that the whole facts showed the necessity for the asylums used for patients with infectious diseases being open to medical students, in order that the appearances of these diseases in all stages should be more accurately known than they appeared to be in the general hospitals. Sir E. H. Currie, for the General Purposes Committee, called attention to the increased need for more accommodation for imbeciles. The asylums at Leavesden and Caterham had many children, and the Darenth committee were called upon to take these; but in the Darenth Asylum for Children there was an excess of 130 cases. In regard to imbeciles generally, the number committed to the charge of the managers had increased from 3652 in 1873, to 5327 in 1883. He moved that steps should be taken to prepare and submit plans for the erection of buildings at Darenth for 500 or more imbecile patients. The motion was adopted unanimously.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5389 births and 3512 deaths were registered during the week ending the 22nd inst. The annual death-rate in these towns, which had been equal to 21·3 and 20·9 per 1000 in the two preceding weeks, was again 20·9 last week. During the first eight weeks of the current quarter the death-rate in these towns averaged 20·7 per 1000, and was lower than in any corresponding period on record. The lowest rates in these towns last week were 17·0 in Bristol, 17·6 in Newcastle-upon-Tyne, 19·1 in Halifax, and 19·4 in Brighton. The rates in the other towns ranged upwards to 25·2 in Nottingham, 25·8 in Sunderland, 26·0 in Wolverhampton, and 26·2 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 392 and 369 in the two previous weeks, rose again last week to 391; these included 76 from whooping-cough, 72 from scarlet fever, 67 from "fever" (principally enteric), 59 from measles, 44 from diphtheria, 40 from diarrhœa, and 33 from small-pox. The deaths from these zymotic diseases caused the lowest death-rates last week in Brighton, Huddersfield, and Bristol; and the highest rates in Bolton, Norwich, and Cardiff. The greatest mortality from whooping-cough was recorded last week in Leeds and Halifax; from scarlet fever in Salford and Sheffield; from "fever" in Derby, Newcastle-upon-Tyne, and Norwich; and from measles in Hull, Halifax, Bolton, and Cardiff. The 44 deaths from diphtheria in the twenty-eight towns included 31 in London, 3 in Liverpool, 2 in Norwich, and 2 in Salford. Small-pox caused 53 deaths in London and its outer ring of suburban districts, whereas no death from this disease was registered in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 580, 669, and 750 on the three preceding Saturdays, further rose to 768 at the end of last week; the new cases admitted declined to 149 last week, from 233 and 199 in the two previous weeks. The Highgate Small-pox Hospital contained 48 patients on Saturday last, 11 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had steadily increased in the nine preceding weeks from 159 to 370, declined to 354 last week, and were so many as 141 below the corrected average. The causes of 94, or 2·7 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Leicester, Bolton, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Huddersfield, Birkenhead, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 22·5, 22·6, and 22·3 per 1000 in the three preceding weeks, rose to 26·2 in the week ending the 22nd inst.; this rate exceeded by no less than 5·3 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 8·4 and 14·3 in Perth and Greenock, to 31·2 in Paisley and 36·0 in Aberdeen. The deaths in the eight towns included 115 which were referred to the principal zymotic diseases, against 116, 98, and 103 in the three preceding weeks; 34 resulted from measles, 27 from whooping-cough, 21 from diphtheria, 14 from

Digitized by Google

scarlet fever, 14 from diarrhœal diseases, 5 from "fever," and not one from small-pox. The rate from these diseases in the Scotch towns last week averaged 4·8 per 1000, and was more than double the rate from the same diseases in the large English towns. The 34 deaths from measles in the Scotch towns showed a further increase upon recent weekly numbers, and included 19 in Glasgow and 10 in Aberdeen. The 27 fatal cases of whooping-cough also showed a further increase upon recent weekly numbers; 9 occurred in Glasgow, 6 in Dundee, and 4 in Edinburgh. The 21 deaths from diphtheria also showed an increase, including 8 in Glasgow and 5 in Edinburgh. Nine of the 14 deaths from scarlet fever occurred in Glasgow; and 3 of the 5 deaths referred to "fever" were returned in Edinburgh. The 145 deaths referred to acute diseases of the respiratory organs in the eight towns showed an increase of 44 upon the number in the previous week, and were 5 above the number returned in the corresponding week of last year. The causes of 89, or 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 24·7, 25·3, and 30·0 per 1000 in the three previous weeks, further rose to 32·7 in the week ending the 22nd inst. During the first eight weeks of the current quarter the death-rate in the city averaged 28·1 per 1000, whereas the rate during the same period did not exceed 19·0 either in London or in Edinburgh. The 220 deaths in Dublin last week showed a further increase of 18 upon the number in the previous week, and included 39 which were referred to the principal zymotic diseases, against 18 and 26 in the two previous weeks. Of these 39 zymotic deaths, 16 resulted from scarlet fever, 7 from "fever" (typhus, enteric, or simple), 7 from whooping-cough, 6 from diarrhœa, 2 from diphtheria; 1 from measles, and not one from small-pox. These 39 deaths were equal to an annual rate of 5·8 per 1000, the rate from the same diseases being 2·3 in London and 4·0 in Edinburgh. The deaths from scarlet fever, which had been 8 and 10 in the two preceding weeks, further rose to 16 last week, and exceeded the number returned in any previous week of this year. The fatal cases of whooping-cough and diarrhœa also showed an increase. The 7 deaths referred to "fever" were two fewer than those in the previous week. Six inquest cases and five deaths from violence were registered, and 70 deaths were recorded in public institutions, showing a marked increase upon recent weekly numbers. The deaths both of infants and of elderly persons were fewer than those in the previous week. The causes of 34, or more than 15 per cent., of the deaths registered during the week were not certified.

"Audi alteram partem."

COCAINE.

To the Editor of THE LANCET.

SIR,—Permit me to add my testimony to the advantages to be derived from the use of a 4 per cent. solution of cocaine in operations upon the eye. It acts excellently as a local anæsthetic, rendering the conjunctiva and cornea insensitive in the course of a few minutes. I first tried it on the 13th inst. in a case of extraction of a cataractous lens at the Royal Westminster Ophthalmic Hospital. It was dropped into the conjunctival sac about four times in the course of twenty minutes. The speculum was introduced, the conjunctiva was seized with the forceps, and the man was asked whether he felt pain. "No, Sir," was the reply. The linear knife was then passed across the cornea, and as it was slowly made to cut its way out, the patient was asked two or three times whether he experienced any suffering. "Not a bit, Sir," he answered each time. I have since tried it on three cases of cataract, in all of which the pain was stated to be inconsiderable though not entirely absent. I further tried it in a case of entropion, the solution being subcutaneously injected; but it did not seem to effect any material alleviation of the pain, perhaps because a sufficient interval of time was not allowed to elapse. On Friday last I operated on a boy of eight years of age for squint. No pain was felt till the tendon was picked up with the hook, when as it was divided the child whimpered a little, because he did not like the scissors. This, however, did not prevent him from submitting, with a little coaxing, to the operation on the other eye. Lastly, I have done one iridectomy for glaucoma under its influence. The application of the forceps and the transfixion of the cornea did not produce any complaint of pain; the division of the sclerotic caused some, but not severe pain. The division of the iris excited no remark. The patient, on being informed that the operation was completed, said, "I was told there would be no pain; there was some, but it did not last long." The partial failure of the remedy in this case may reasonably be referred to the difficulty with which absorption takes place when the eye is very tense. On the whole I am well satisfied with the effects produced, and consider that it will prove of the greatest benefit to those who are old and infirm, or who from any other reason object to the use of chloroform or ether. In general surgery it will probably prove useful in cases of stricture, and as an anæsthetic in the removal of dressings. It does not seem to produce any disagreeable after-effects.

I am, Sir, yours truly,

Cumberland-place, W., Nov. 1884. HENRY POWER, F.R.C.S.

To the Editor of THE LANCET.

SIR,—As an addition to the information given by my friend, Dr. Felix Semon, last week, on the effect of cocaine on the larynx, will you allow me to publish the effect of cocaine on the interior of the nose? The experience is all the more valuable, because it is personal; the nose which was operated on was my own, the operator was Dr. Semon.

About three weeks ago, Dr. Semon was kind enough to apply the galvano-cautery freely through the thickness of the mucous membrane over my right inferior turbinated bone, as for some time past I have suffered from slight symptoms of obstruction, which, I thought, might cause or at least aggravate the attacks of migraine from which I occasionally suffer. He made three long incisions in the membrane. They produced so much pain that I found it difficult, even with great determination, to sit still. My right eye ran with water and the conjunctiva was instantly intensely congested. The application of the cautery to the turbinated bone immediately lighted up the pain on the right side of the head and in and behind the eye, such pain as I always experience during an attack of migraine. I was very unwell during the rest of the day, and on the day following was laid up with the most violent attack of migraine I have ever had. On these accounts it was agreed that when the operation was repeated I should take gas or chloroform. In the meantime we have become acquainted with the properties of cocaine, and Dr. Semon has, as he has already told you, put it to the test in affections of the larynx. To-day he repeated the burning of my nose, and, instead of three linear cauterisations, made five—two in the inferior and three in the middle turbinated bone. But, instead of using gas or chloroform, he first painted the surface of the bones thoroughly twice with a 20 per cent. solution of cocaine, allowing an interval of five minutes to elapse between the first and second paintings, and another interval of five minutes between the second painting and the burning. The effect was marvellous, far more so than I, or even he, I think, expected. The burning was not felt by me more than the introduction of the brush in painting. I cannot say I did not feel the operation, but the sensation must be described as feeling, not pain; for indeed I suffered none. There was scarcely any watering of the eye or suffusion of the conjunctiva, and there was no pain in the head or about the eye. Of the length of time during which the effect of the cocaine lasts I am not able to speak, for although after the first operation I was much more unwell than I feel at present, there was really very little pain in the nose. Certainly the discomfort has been less this time, and the cocaine has not left any disagreeable sensations.

Dr. Semon begs me to draw attention to the strength of the solution of the muriate of cocaine which was used—20 per cent.; very much greater than the strongest solution which is used in ophthalmic surgery. At an earlier hour on the same morning he performed the same operation on the turbinated bone of a patient (a medical man) who brought with him a 4 per cent. solution of cocaine. The pain was less than if no local anæsthetic had been employed, but was

Digitized by Google

not entirely absent, as in my case. I can confirm this observation so far that on the previous day I used a 4 per cent. solution in operating on the larynx of a delicate woman under my care at St. Bartholomew's Hospital without producing any marked anæsthesia. Yet the application was made twice, and an interval of at least five minutes was allowed between the applications and between the second application and the operation. It is not improbable that a solution of less strength than 20 per cent. will suffice in operations in the interior of the nose, and this will easily be determined during the next few weeks or even days. Indeed, the sooner it is determined the better, for the muriate of cocaine is at present extremely expensive, costing about one shilling a grain. When the 20 per cent. solution is employed, and the nose or larynx is brushed over twice thoroughly, it will be found that from two to four grains of the cocaine have been used. I am informed that the cost will probably increase during the next few months if the drug is as largely employed as it bids fair to be, for the supply is very limited, and there is not even a good prospect of obtaining a sufficient supply of the leaves from which the alkaloid is manufactured.

Nov. 24th (two days after the operation).—Yesterday I suffered from a slight attack of migraine, not so severe as I have often experienced, and not to be compared with that which followed the first cauterisation. To-day it has completely passed off, for it only lasted a few hours. How much of the difference is to be attributed to the use of the cocaine I am not able to say, but I believe a part of it at least. I mention it to make the case as complete as possible, and to show that there is certainly no reason to apprehend that the after-effect of the alkaloid will exaggerate the suffering of the patient. I remain, Sir, yours truly,

Queen Anne-street, W., Nov. 24th, 1884. HENRY T. BUTLIN.

P.S.—Dr. Semon has just looked through this letter, and thinks I ought to have offered some explanation of the reasons which induced him to perform and me to submit to the cauterisation of the turbinated bones for migraine; but I think it will be better to defer that and the discussion of Hack's theory to a later date, when we have more material within our reach. The object of the present communication is to direct attention to another use of cocaine.

FLUKES IN MAN.

To the Editor of THE LANCET.

SIR,—Having received from Dr. Manson a copy of Dr. Wallace Taylor's paper entitled "Distomata Hominis," I request permission to offer a few criticisms in no unfriendly spirit. Dr. Taylor says that "the whole subject of distomata infesting man has probably been worked up better in Japan than elsewhere." Nevertheless his memoir, which from the clinical standpoint does him much credit, omits all reference to the labours of Lewis, McConnell, Sonsino, Thomas, and others. My papers on Distoma crassum, Bilharzia, &c., naturally share the same fate.

Dr. Taylor gives a description of Distoma Ringeri, but, following Prof. Baelz, he calls the parasite D. pulmonale. My description of the original fluke sent by Dr. Manson was published in the *Quekett Journal* in 1880, two years before the publication of Baelz's memoir in the *Berliner Klinische Wochenschrift*, which he quotes (1883). Baelz, it seems, had mistaken the eggs of this fluke for gregarines.[1] But apart altogether from the question of priority, the title (D. pulmonale) is badly chosen, because the lung flukes of mammals are so very like one another. The D. compactum found by me in the lungs of the Indian ichneumon is apparently a mere variety of, if it be not identical with, D. Ringeri of man, and as much may be said of Dr. Kerbert's D. Westermanni infesting the lungs of the tiger.[2] In all three corresponding forms the uterine organs have precisely the same character and disposition. Certainly Baelz's and Kerbert's figures leave little to be desired.

The second parasite described by Dr. Taylor is still more unfortunately named. He calls it D. hepaticum. Here, again, he follows Baelz, who had previously called it D. hepatis perniciosum. It seems incredible that anyone writing on flukes should be unfamiliar with the natural history and characters of the common D. (Fasciola) hepaticum so beautifully worked out by Professor Thomas, and already known to have been detected some twenty times in the human subject; yet Dr. Taylor naïvely remarks that "whether D. hepaticum hominis is of a different species from the Fasciola hepatica (Linn.), well known in Europe as the cause of the sheep 'rot,' I am unable to decide." Dr. Taylor's parasite (D. hepaticum hominis) is utterly unlike the common liver fluke. If it be a good species, it will be less confusing to call Baelz's fluke (D. Baelzi). My impression is that it is only a contracted or broad example of the species which I have called D. sinense. Dr. Taylor, however, says of his D. hepaticum that, "omitting minor differences, the general description given of the viscera of the D. pulmonale will answer for this." This statement surprises me, for his own, or rather Professor Baelz's, really good figures show that (as regards the position and extent of the vitellaria and other reproductive organs) no two fluke species of the same genus could well be more divergent in the arrangement of their essential organs.

The next species described by Dr. Taylor is Prof. Baelz's so-called Distoma hepatis innocuum. This fancied new parasite is (as Manson himself points out in a pencilled side-note) nothing more than the now well-known D. sinense, of which I have specimens sent by the original discoverer, Prof. McConnell. Unaware of my prior description, Leuckart named the same parasite D. spatulatum. I have part of a liver well infested by this fluke, which is doubtless "pernicious" in its effects. Baelz's zoological nomenclature is therefore altogether inadmissible.

Dr. Taylor's memoir closes with figures of two other fluke parasites. Here again he is equally unfortunate in his determinations. The large fluke "infesting the stomach of cattle," which he calls a distoma, is the well-known Amphistoma conicum, whilst the smaller fluke, taken from the liver of a cat, is probably Creplin's Distoma conus. The size, to be sure, is rather larger than Dujardin states it to be in his description.

The errors which exist in regard to the synonymy of parasitic species are already sufficiently burdensome, and it was in the hope of aiding identification that I published a "Manual of Reference" to all the known human parasites, bringing the literature up to date (1882). Honest and good workers, who are not at the same time systematists, can have little idea of the great trouble and confusion which the introduction of new names for old or familiarly known parasites creates in medicine. Solely in the hope of checking errors of fluke-nomenclature in relation to important diseases I have made these few remarks, which I trust will be accepted in the spirit in which they are offered.

I am, Sir, your obedient servant,

Portsdown-road, W., Nov. 22nd. T. SPENCER COBBOLD.

"CHARCOT'S JOINT DISEASE."

To the Editor of THE LANCET.

SIR,—The interest excited by the discussion at the Clinical Society on "Charcot's Disease" induces me to state that you published in THE LANCET of Jan. 28th, 1871, in a report by me of cases under the care of Dr. Charcot at La Salpêtière, Paris, the first notice of this disease in England. This report included a very short *résumé* of the clinical facts, and by what, in considering the diagnosis, rheumatism was excluded. In 1876 I begged of Dr. Charcot that he would kindly give some specimens of bones illustrating the disease in question. He informed me that the specimens he had shortly before had at his disposal were sent to the museum of St. Thomas's Hospital. May I here have the pleasure to acknowledge that Dr. Charcot did not send me empty-handed away, but gave me sections of the spinal cord in another form of disease—namely, progressive muscular atrophy, which I exhibited at the Pathological Society May, 1877, as having a relationship with the joint affection.

I append an extract from your journal of the date above named.

I am, Sir, your obedient servant,

Stratford-place, W., Nov. 1884. T. W. NUNNELEY.

"Dr. Charcot pointed out some cases of joint affection which he believed showed that consecutive to lesion of the nervous system arose mischief in the joints. In the *Archives de Physiologie* No. 1, 1868, he has published papers: "Sur quelques Arthropathies qui paraissent dépendre d'une Lésion du Cerveau ou de la Moelle Epinière." "Th[illegible]

of these papers is to describe certain phenomena which are occasionally to be observed during the progress of disease of the nervous centres; and he divides into two groups the joint affections which respectively occur during the progress of locomotor ataxy, and in hemiplegia dependent on disease of one of the cerebral hemispheres."[1]

ENGLISH DEGREES FOR ENGLISH STUDENTS.

To the Editor of THE LANCET.

SIR,—Not only practitioners and students, but all patriotic Englishmen, must agree with the remarks in your leading article of November 1st on the continuous exodus of English medical students from their native schools. This is a matter with which pecuniary considerations have absolutely nothing to do, as at the present day the necessary expenses of medical education vary little on either side of the Tweed, and the fee for the double degree of M.D., M.S., in the North is about the same as that for the usual double qualification in London. I brought this subject forward at the meeting of the Royal College of Surgeons in March last, and then drew attention to the rapid decadence of the English schools of medicine. There is no doubt whatever as to the cause of this. The real explanation, as I then pointed out, is the fact to which you allude, that "no more learning is needed and no greater effort demanded to obtain a diploma of doctor of medicine in other places than is required in London and most of the English schools to obtain a mere licence to practise." This is, indeed, an understatement of the facts, for in all that concerns medical knowledge and experience much more is demanded of a candidate for the English licence than of a candidate for a Scotch degree, as may be seen by anyone who will compare the regulations of the examining bodies.

A glance at the Medical Directory will show that about 2000 practitioners suffice for the medical requirements of the whole of Scotland, whilst there are more than twice that number in active practice in London alone, and six times the number in addition in the English provinces. But at the medical schools in Scotland there are probably twice as many students as at all the medical schools in London; a considerable proportion moreover of those entering at the London schools find out afterwards the mistake they have made, and go off after one, two, or three years to other schools where their labours will be more fitly rewarded. The result is that the English licentiate is everywhere thrust aside by the Scotch graduate, and elbowed out of office, employment, and profit; every honorary medical appointment is closed to him by the universal rule admitting only graduates, and he is necessarily relegated to a secondary rank, and is thus and thus only prevented from rising to such a professional position as he might otherwise attain, and to which his qualifications and abilities would give him an indisputable right. There is an easy and natural remedy for this state of things without calling upon the London or any of the other universities to lower its standard, and without adding to the excessive number of licensing bodies already existing. At the meeting to which I have referred I proposed that the two Royal Colleges of Physicians and Surgeons should be amalgamated into one great Royal College of Medicine, to be endowed with the power of granting the degrees of M.D. and M.S.[2] (see the report in your issue of March 29th). There is no need to call the United College a University, nor would there be any advantage in doing so. There is nothing either novel or incongruous in a college granting degrees; various instances might be cited from both ancient and modern times, but it will suffice to mention the University of Edinburgh, which was only spoken of as a college for more than a century after its foundation, and which, as Sir Alexander Grant says, "never did and never could become a university in the mediæval sense of the term." Oxford, and Trinity College, Dublin, are now the only universities requiring the B.A. to be taken previously to the M.D., so that as far as medicine is concerned the College of Physicians is practically on exactly the same footing as any of the other universities—it prescribes a curriculum, conducts an examination in, and grants a diploma for, medicine, which is a licence to practise. The moment a university medical degree is dissociated from an Arts degree, and allowed to become a licence to practise, it ceases as such to be anything more, and the whole of its value as a higher title will depend on the character and standard of the particular curriculum, and examinations of which it is the end and aim. It cannot surely be difficult for a committee of both Colleges to prepare a scheme of complete union which shall be satisfactory to the English profession. The mere conjunction of the Colleges for examination purposes will not retain students at the London Schools nor make the London qualification more attractive; and if the fees remain exactly as in the separated Colleges, there can be no conceivable advantage to the English student in a mere conjoint board at all. Although the question of expense enters very little into this question of the driving away of students from the London schools, yet so large fees, being charged for primary examinations must rather deter than attract students, and one sees no reason why either College should now charge ten guineas for exactly the same examination that each before charged five guineas for; it would have been far better to continue to charge five guineas for each primary examination and twenty-five guineas for the double pass examination; but a little more liberality in this matter of fees would disarm much opposition to the scheme, and would probably result rather in a gain than a loss in a pecuniary sense.

The present is a great opportunity. On the boldness or hesitation of those who influence the affairs of our two Royal Colleges depends the continuance of the success of our English Schools of Medicine—depends probably the future existence of the Colleges themselves.

I am, Sir, yours obediently,

WILLIAM HICKMAN.

Dorset-square, N.W., Nov. 16th, 1884.

"OVER-PRESSURE IN SCHOOLS."

To the Editor of THE LANCET.

SIR,—In THE LANCET of Nov. 15th there is a leader on the above subject. Your remarks are well timed and essentially to the point, and I believe that there are few members of our profession who will be found to disagree with their general tenour. The subject is one of vital importance to the future well-being of the nation, and it is a subject, moreover, in the settlement of which the medical profession is peculiarly concerned, for it is impossible, in my opinion, for anyone who has made the nature of disease a study and its treatment a practice, to remain in ignorance of the fact that the present system of education is being maintained at a ruinous, and to the general public, almost inexplicable expense. The expense is not a monetary one, but consists in the wasted energies and premature deaths of children, who, in other and more reasonable circumstances, might have lived long and useful lives. To the members of our profession whose daily work brings constantly under observation the relations which the various parts of the human frame bear to one another during life the difficulties which at present roughen the educational road are easily apparent; but it is otherwise with the general, and, as a rule, unthinking mass of the population. The average parent desires that his children shall be educated as speedily, as cheaply, and as thoroughly as possible; and he naturally regards with favour a system of education which endeavours to make up for lack of time by an increased amount of material, and it is with feelings of pride that such a parent will tell admiring friends that his boy of ten is almost fit to leave school, and has his head stored with a wonderful amount of learning. The boy often begins to fag and to fall into a state of ill-health which is misunderstood by both parent and schoolmaster, and the educational mill is allowed to grind into dust all the fair promises of early boyhood, and upon the very threshold of life this prodigy of youthful learning falls. His brain, over-driven and exhausted, is like a jaded horse, dull and irresponsive at a time when its best efforts are required, and his body, neglected and forgotten, fails with sad and ominous frequency in the performance of its duties; and, in a word, a wasted life is the result, the inevitable result, of a premature and excessive demand upon the higher functions of the human frame. This is, perhaps, a somewhat gloomy picture, but if we consider for a moment the delicate and easily disturbed organism over which the relentless educational Juggernaut is driven, the reason for

[1] THE LANCET, Jan. 28th, 1871, p. 117.

[2] To the title "Royal College of Medicine," the words "and of Physicians and Surgeons of England" could be added as a secondary title if thought desirable, to satisfy the scruples of some who might regret to part with these time-honoured designations.

Digitized by Google

the gloom will perhaps become apparent. The labours of Ferrier and other workers in the field of the higher neural physiology have made it plain to us that the brain is to be regarded as the organ of mind, and that in the present state of our knowledge it is useless to consider even the most exalted thought, feeling, or imagination as phases of mental action which are apart from or above or independent of the change and interchange of material atoms. If we look upon the brain, then, as analogous to any other part of the human frame—as a muscle, for example—we shall easily conceive of its being over-excited and over-wrought, and as a consequence exhausted, and even in process of time altered in its structural elements. A muscle, we know, becomes hypertrophied by over-use, and, if timely rest be not obtained, will also atrophy and decay. But how much more delicate is the brain than any other organ of the animal economy? It is so delicate that nature, always provident and far-seeing, has provided for its protection a covering which combines lightness and strength in a degree never attained by any work of man. The minute and variously shaped cells, the fine network of nervous tissue, the subtle fluids, and the fragile and easily inflamed investing membranes, all have a part to play in the formation of every phase of mental action, and all become more perfect or inapt in the performance of their parts as the years pass by. Education, if one were permitted to describe so important a subject in a phrase, *is essentially a physical process.* The brain and body ought to be regarded as one to be educated together, and to grow in usefulness together. There is but one distinction worthy of present notice: the former is more easily deranged in its action and altered in its structure than the latter. Spencer, in his essay upon Education, remarks that the ancients educated the body and forgot the mind, while we in our day educate the mind and forget the body, and advises a combination of the ancient and modern conceptions of education.

The evils of over-pressure are at present only apparent to the few, and even by the few their extent cannot be estimated. It is to the future that we must look for the direst result of the present system of education.

I am, Sir, your obedient servant,

Glasgow, Nov. 18th, 1884. ROBERT MACPHERSON.

ANTISEPTIC SURGERY.

To the Editor of THE LANCET.

SIR,—I enclose a sketch of rules observed, in their main features at least, by many German and Austrian surgeons; and I cannot help thinking they will be quite novel to most in this country. Statistics are not of much use, of I could quote some remarkable series of abdominal operations without deaths in which these rules were rigorously observed. In private practice much of this elaborate care is impracticable, but I venture to believe that one single rule is almost alone requisite. It is this: Let the air be as free from dust as possible, and allow nothing to be brought in contact with the wound, or parts near, which is itself impure, or has touched any doubtfully pure surface. How far this can be carried out without special training is another matter.

I am, Sir, yours faithfully,

A. OGIER WARD,
Tottenham, Nov. 17th, 1884. M.B. and C.M. Edin.

RULES OF ANTISEPTIC SURGERY IN GERMANY AND AUSTRIA.

1. *The Operator and Assistants.*—During the previous twenty-four hours they should not have made any post-mortem or anatomical dissections or vaginal examinations, nor have attended any infectious cases; but if any of these rules have been run, extra cleansing of the person is demanded. On the day of operation care is taken that no scurf shall fall from the head, and the beard is carefully attended to. At the time of operation the coat is removed (also collar and waistcoat in some cliniques), and a clean apron or short-sleeved linen jacket is put on, the arms being bare to the elbows. Hands and arms are washed, first in hot water, then in a corrosive sublimate solution, 1 to 2000, or else in 1 to 20 carbolic solution, and the nail-brush is diligently employed for the entire hands and arms, not for the nails alone. A basin of this solution is in frequent use throughout the operation, and if anyone touches any unsanctified object, he must again wash his hands and not merely dip them. In some cases the coats and hats are excluded from the room, and care is demanded that the boots shall be as clean as possible.

2. *The Room.*—This is thoroughly washed all over with carbolic soap as shortly before the operation as may be practicable, and the spray is often used for some time before the operation.

3. *The Apparatus.*—The instruments are most carefully scrubbed with 1 to 20 of carbolic solution, the handles receiving great attention, and they lie soaking for a considerable time beforehand, if feasible. The protective, if employed, is also soaked before use. The outsides of all bottles, syphon-tubes, syringes, &c., are washed with one or other antiseptic; and tourniquets, Esmarch's bandages, and so forth, all come in for attention. The usual porcelain trays are used to hold the apparatus, and are liberally supplied with carbolic or sublimate solution.

4. *The Patient.*—The patient is cleansed as far as possible before being brought into the room; and, if a limb is to be operated on, it is wrapped in a solution for some hours previously. When laid on the table the patient may be enveloped in a blanket; but if so, that is scrupulously covered by waterproof sheeting, the outside of which is sponged over with some solution. The exposed limb or part is now scrubbed with sublimate solution, then shaven and again washed. Now, all who have had to handle these unclean surfaces repeat the scrubbing of their own hands, and the operation commences.

5. *The Operation.*—No instrument, or appliance of any sort, is allowed to touch the patient unless both it and the hands of the assistant are absolutely beyond suspicion. Thus, if the assistant rests his hand on the table, the operator will not take an instrument from that hand until it has been washed, not dipped. In fact, the guiding principle is that nothing shall touch the open wound which, either primarily or secondarily, has been in contact with an unclean surface. The dressings vary with the fancy of the operator. Iodoform glycerine, 1 to 20, figures largely, as also iodoform gauze. It is customary to cut away the outside foot or so of any carbolised bandage, and the outer surface of a fresh mass of salicylic wool is never allowed to be placed next the skin.

REGINA *VERSUS* C. F. J. B. BRIGGS AND ELIZABETH BRIGGS.

To the Editor of THE LANCET.

SIR,—I beg to call your attention to this case, wherein it appears that a very serious miscarriage of justice has taken place.

At the last Nottingham Assizes a man named Briggs and his mother were tried for the murder, by starvation, of Thirza Briggs, the wife of the male prisoner. I enclose you a newspaper report of the trial and notes of the evidence. It was proved that the mother-in-law of the deceased behaved with great cruelty to her, and that the husband (a weakly and nearly blind man) did not supply his wife with food. It was proved, however, that the deceased had silver in her possession, and that she procured food from her neighbours during the six weeks immediately preceding her fatal illness; also that she had as recently as July been staying some weeks with friends, where, it was admitted, she had everything she required. On Sept. 28th she fell down in a fit, and on Oct. 3rd she died comatose. A post-mortem examination was made and an inquest held, when a verdict of wilful murder was returned against the two prisoners. At the trial two medical men, who had made the post-mortem, swore that the deceased died of serous effusion on the brain, the result of starvation. On that evidence the male prisoner was found guilty of manslaughter and sentenced to twenty years' penal servitude.

Now, Sir, I venture to state that the post-mortem examination entirely failed to prove starvation, and that the sworn facts of the case were absolutely incompatible with starvation.

I am, Sir, yours obediently,

The Sanctuary, Nov. 25th, 1884. THOS. BOND, F.R.C.S.

THE REMOTE EFFECTS OF GOUT.

To the Editor of THE LANCET.

SIR,—I read with much interest the description of the relation of certain diseases of the eye to gout, as reported last week in THE LANCET. Mr. Hutchinson has remarked in his lecture on the obscure non-arthritic effects which gout

Digitized by Google

may produce in the children of gouty parents, without any ordinary gouty symptoms. I have had two cases lately in my practice which illustrate his remarks so well that I cannot forbear from quoting them. A Mr. H—— came to me suffering from chronic eczema and psoriasis. He attributed it himself to the great changes of temperature and profuse perspirations incidental to his business. I put him on arsenic and afterwards on iodide of potash, without much benefit. He told me that he had never had any gouty symptoms in his life. Shortly afterwards his married daughter, Mrs. B——, consulted me on certain intense pains in her eyes, accompanied by temporary congestion and partial blindness, which attacked her whenever her digestion was deranged. Recognising this to be a gouty symptom, and bethinking me of the obscure skin disease which afflicted the father, I made somewhat minute inquiries into the previous family history. I then found that the grandfather of Mrs. B—— and the father of Mr. H—— had been a martyr to gout for many years, and had eventually died of a form of Bright's disease, which I have no doubt from the description was the "contracted granular kidney" so intimately associated with gout.

These cases are, I think, interesting as showing the protean character of the disease, extending over three generations. The grandfather was thoroughly gouty; the father had skin affections without any other gouty symptom; the third generation exhibited eye symptoms and nothing else. I may mention that both cases improved rapidly upon colchicum and alkalies.—Yours sincerely,

Southsea, Nov. 24th, 1884. A. CONAN DOYLE, M.B., C.M.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE.

OUR mayor has published a letter he has received from Mr. John Hall of this city, in which the latter states that seeing the sum of £10,000 is likely to be required for the extension of the infirmary, he will with pleasure contribute £1000 to the object, and at the same time he makes the laudable suggestion that the work should be carried out now, when so many are out of employment and material is so cheap. A statement has been going the round of our papers contrasting the rate of increase in the legal and medical professions during the last ten years; and it is pointed out that whereas the ranks of the law have increased at the rate of 17 per cent. those of the medical profession have been augmented only at the rate of 3 per cent. These figures may hold good in a general way, but scarcely in particular instances. In Newcastle and its vicinity, for instance, there has been a marked increase lately in the number of medical practitioners; indeed, it is a general remark that we are over-stocked, and in this way it may be questioned if a medical school in a moderate-sized provincial city is an institution to be desired by the resident practitioners as an unmixed blessing.

NORTH SHIELDS.

The Duke of Northumberland has in the most generous manner made an offer which is little other than a gift to the North Shields Corporation of an important portion of land for the purpose of forming a public park on the Tynemouth-road. The Duke has at the same time urged that the present was a most opportune time for laying out the land and giving employment to a large number of people.

THE SMALL-POX EPIDEMIC AT DURHAM.

At a special meeting of the Durham Town Council lately held in connexion with the small-pox epidemic it was stated that the town was not nearly so bad as represented, and that the disease would soon be stamped out. That the epidemic is bad enough is evident from the fact that there are thirty-four cases in the hospital just opened. It is certain, also, that small-pox cannot be stamped out by the distribution of handbills, however useful in their way. A correspondent points out that the police ought to endeavour to repress juvenile ignorance and temerity in riding behind the carriage used to convey the small-pox patients to the hospital, that he was distressed to see so many children gathered together at a passage end to see a patient brought out, and on making inquiry he found that there were no fewer than five cases down the same passage, and he asks, "Can it be wondered at that the disease is spreading?"

SCARLET FEVER AT WALLSEND.

At the usual monthly meeting of the Wallsend Local Board last week Dr. Henry Aitchison, the medical officer, reported that the death-rate for the past month was equal to an annual rate of 39 per 1000. Fully one-half of the deaths reported was from scarlet fever of a malignant form, which was still epidemic.

GATESHEAD PENNY DINNERS.

I mentioned in a previous communication the success of the Rev. Moore Ede, Rector of Gateshead, with his system of cheap meals for school children. He has now further developed his method so as to provide cheap meals for the working classes. The foundation of his system is "No charity, no pauperisation," therefore nothing is sold under cost price; nevertheless, he has found that, owing to economy of fuel and labour, as well as to the larger amount of nutriment extracted by the cooking apparatus employed, he can supply excellent nutritious soup at the price of ordinary soup kitchens—viz., one penny per quart. The number of dinners has increased from half a dozen to 100 per day, and the demand for soup and other articles for home consumption is daily increasing. The following is an example of the bill of fare:—Pea-soup, lentil-soup, potato stew, and raisin pudding. Wholemeal bread is supplied at the rate of fourteen ounces for 1*d.*; in fact, a good meal for a working man with a hearty appetite is supplied for 2*d.*, including stew or soup and pudding. As to the economical aspect, Mr. Ede gives his figures, which show that since the commencement of the experiment the amount spent on materials was £24 14*s.*, while the receipts were £32 13*s.* 4½*d.*, leaving as a balance £7 19*s.* 4½*d.*, considerably more than was required to pay wages and gas for heating, so that by the end of the year he hopes to have a handsome balance to hand over to the Distress Relief Fund.

Newcastle-on-Tyne, Nov. 26th.

IRELAND.

(From our own Correspondent.)

ACADEMY OF MEDICINE IN IRELAND.

THE opening meeting of the Medical Section took place on the 21st inst. at the College of Physicians, when Dr. Cruise, President of the College, delivered the inaugural address. He principally referred to the conflict which occasionally took place between law and medicine, and dwelt at considerable length on the loss of time and money occasioned to practitioners for attendance on patients whose affairs were relegated to the Court of Chancery. Dr. Cruise gave several typical cases illustrative of the hardship he had suffered, and where fees in some instances were altogether lost or reduced by the taxing master, and said that for such treatment medical men practically had no redress.

ROYAL COLLEGE OF SURGEONS.

The new scheme of education and examination for the diploma in Surgery of this College has now been in operation for some time, and the longer it exists the more it is disliked by all who have to do with it. There is a very large section not alone of Fellows but of the Council who now consider it an ill-advised scheme, and one which will require to be amended very materially before the principal objections to it can be removed. I am confident a large number of those who voted for it formerly would now oppose it if brought forward, and it is a subject of considerable regret that the scheme as it at present stands was ever introduced. Several candidates for the Second Professional Examination having been stopped in October last, they recently petitioned the Council for a supplemental examination; and this the Council at a meeting held last week have granted. The examination will take place in March next, and the candidates will be allowed credit for the various lectures and hospital they may take out this session. I may add that of forty candidates for this examination in October, no less than twenty-two were rejected.

DEATH OF DR. LESLIE MATURIN.

This gentleman, who was resident physician to Cork-street Fever Hospital, Dublin, died last week after a short illness

Digitized by Google

from malignant scarlatina, aged thirty-five. Dr. Maturin was formerly surgeon-superintendent of the Emigration Department, New Zealand, and afterwards surgeon to the Red Cross Society, Russo-Turkish War of 1877-78. Skilful and kind, his untimely death is much regretted by a very large circle of friends.

IRISH PRISONS BOARD.

It is rumoured that Sir John Lentaigne, an unpaid member of the board, has recently sent in a report to the Lord Lieutenant, in which he suggests a board without the introduction into it of a medical member, and contrary to the recommendation of the Royal Commission. On the other hand, another member, Mr. O'Brien, who does not belong to the medical profession, is of opinion that an independent medical gentleman should be a member of the Irish Prisons Board, and not merely an official under it.

THE SALARY OF THE CORONER FOR DUBLIN.

The coroner, Dr. Whyte, recently applied to the Corporation for an increase of salary—viz., from £500 to £600 a year, but the application was refused to be entertained. Last week, before Mr. Justice Johnson in the Queen's Court Division, Dr. Whyte, through his counsel, applied for the increase. An objection was lodged that sufficient notice had not been given, but ultimately this was waived. Mr. Justice Johnson said the Act provided that when the Corporation and the coroner could not agree as to the amount of salary, the coroner should refer the matter to the Chief Secretary, and as that had not been done the Court could not interfere. Later in the day it was suggested that the Corporation might consider the propriety of granting a sum as salary for a clerk, but as it was too late for the present city presentments, the matter fell through.

THE RIVER LIFFEY.

The Corporation have adopted a report of the Public Health Committee in reference to the nuisance caused by the discharge of sewage into the Liffey. Pending the carrying out of a system of main drainage the committee are of opinion that the only way of completely abating the nuisance is the scavenging of the river bed during the summer months, and the more effective employment of disinfectants. They recommend the annual grant for that purpose to be increased from £200 to £500. The expenditure of £200 last summer had no effect in abating the intolerable stench, and it is doubtful if the larger amount will produce a better result.

Dublin, Nov. 25th.

BELFAST.

(From our own Correspondent.)

THE ROYAL HOSPITAL.

THE annual meeting of the subscribers of this deserving charity was held on Monday, Nov. 17th. From the report we gather that during the year 2181 intern patients have been treated, being an increase of 182 over last year, and considerably in excess of the number ever before treated in the hospital. There were also treated 11,765 extern patients, showing an increase of 1201 on last year. The intern and extern cases together number 13,946. Clinical instruction has been given in the wards to 168 students during the winter, and to 88 during the summer session. Lord Ashley has been elected President of the hospital in place of the late Marquis of Donegal. During the year the sum of £533 12*s.* 3*d.* has been received from sixty-one churches, this sum being £13 8*s.* 6*d.* less than the amount contributed the previous year. There is also a slight falling off in the general subscriptions during the year. The donations and bequests have also decreased, the sum being £899 12*s.* 6*d.* less than the previous year. The two cheering features in the accounts are the continued increase in the subscriptions of the working classes and the result of the Hospital Saturday movement. Last year the working classes increased their subscriptions by the sum of £580 16*s.* 2*d.* This year there is a further increase of £680 14*s.* 11*d.*, bringing up the total contributions of the working classes to £1692 3*s.* 7*d.* From the efforts made on Hospital Saturday a sum of £529 15*s.* 9*d.* was raised. The total expenditure on the hospital for the year was £8051 11*s.* 7*d.*, and notwithstanding all the efforts put forth, there is a deficit of £1791 10*s.* 1*d.* During the year several of the wards of the hospital have been refloored and refurnished, and at present, through the munificence of Mr. Robert Dunville, D.L., several other wards in the centre of the hospital are being refurnished, while Mrs. Dunville is most generously fitting up new rooms for the out-patients in connexion with the department for the diseases of women.

The Grand Bazaar and Fancy Fair in aid of the Royal Hospital was opened on Thursday. The main hall was transformed into an ambulance encampment, the tents being used as stalls for the sale of goods, while in the annexe marquee there was a great variety of entertainments. In the minor hall the private theatricals were largely attended. There is to be a fancy dress ball on Tuesday, Dec. 2nd, in connexion with the hospital bazaar. It is hoped that by the efforts put forth at the bazaar a large sum of money will be raised for the hospital, and that the present debt will be much more than extinguished.

PRIVATE HOSPITAL ACCOMMODATION.

The want of an institution of this kind for women having been experienced in Belfast, a hospital to supply the need has been opened in Regent-street, and is now ready for the reception of patients. It is intended for those who are able and willing to pay for the accommodation, and who, if they so desire it, can be attended by their medical adviser. All kinds of accidents and diseases except infectious cases will be received. The careful nursing and diet with the privacy of their own homes are advantages which will be eagerly sought after, and it is confidently expected that the applicants for admission will be very numerous.

OPENING OF THE WINTER SESSION.

The present winter session began in the first week of November, and the classes at the College and the cliniques at the hospital are now in regular working order. The opening meeting of the Queen's College Literary and Scientific Society was held on the 21st inst., and the College Musical Society will shortly give their first concert.

DEATH OF DR. MARTIN.

I am sorry to have to announce the death of this member of the profession, who for a period of sixteen years held a dispensary appointment in Belfast. Dr. Martin was a man highly respected by his patients, and for his public appointment a very active canvass is being made.

THE ULSTER MEDICAL SOCIETY.

The first meeting of the above Society for the present session was held on Nov. 11th. The retiring president (Dr. Dill) having given a short address, the incoming president (Mr. John Fagan) read a very interesting and practical paper. The annual dinner took place on Tuesday evening.

PARIS.

(From our own Correspondent.)

THE CHOLERA EPIDEMIC.

THE cholera epidemic in Paris is decidedly on the decline, as shown by the official reports daily published, which I need not trouble you with. I may, however, transcribe those for the last three or four days to give your readers an idea of the course of the epidemic:—

	Admissions.	Deaths.
November 20th	42	20
,, 21st	15	63
,, 22nd	27	10
,, 23rd	20	19

These figures comprise the admissions and deaths in town and in the hospitals. On the evening of the 21st there were 274 (168 males and 106 females) choleraic patients under treatment in the hospitals. On the 22nd the number was reduced to 221. On the 24th there were 2 deaths in town and 6 in the hospitals; but there were no fresh cases reported, as the bulletins have ceased to be published. It has already been brought to notice that the ill-fed and intemperate were the readiest victims of the disease. In a report by Dr. Watelet, who was deputed to inquire into the origin of the cholera in the Asylum for the Aged in the Avenue de Breteuil, this physician declared that he could not trace its origin, but that the rapid spread and fatality of the disease among its inmates were probably due to unwholesome food, and as this consists of the remnants collected from the different hotels and restaurants, the possibility of the food thus obtained

Digitized by Google

being infected with cholera germs has been suggested. Be this as it may, a rapid diminution in the number of cases was observed as soon as the diet of these poor people was improved in quality as well as in quantity. With the active measures that are being taken to improve the sanitary condition of the town it is to be hoped that the epidemic will soon entirely die out.

DEATH OF PROFESSOR FONSSAGRIVES.

The death is announced of Professor Fonssagrives, on the 21st inst., from an attack of cholera which carried him off in a few hours at his château near Auray, in the department of the Morbihan, whither he had retired some months ago owing to failing health. His friends and medical attendant were at a loss to know how the lamented physician could have contracted the disease, as his residence is situated in the open country far from any town, and he had had no communication with any cholera patient. Dr. Fonssagrives was for a long time Professor of Hygiene at the Faculty of Montpellier, and since his retirement he did nothing in the way of practice, but occupied himself a great deal in writing. He was the author of several works, among which his "Traité d'Hygiène navale" is the most recent, and is held in considerable esteem. But his principal work is his "Traité de Thérapeutique et de Matière Médicale," the second edition of which is in the press. Dr. Fonssagrives was a corresponding member of the Academy of Medicine. He commenced his professional career as a naval medical officer, and at the age of thirty he was appointed Professor of Therapeutics at the medical school at Brest. He was born in 1823.

Paris, Nov. 26th.

THE SERVICES.

WAR OFFICE.—Medical Staff: Brigade Surgeon R. W. Carter is granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major D. Renton, M.D., is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-General Alexander Smith, M.D., C.B., and Surgeon-General Jones Lamprey, M.B., have been placed on retired pay.

INDIA OFFICE.—The Queen has approved of the retirement of the following officers of Her Majesty's Indian Military Forces:—Brigade Surgeon Charles Kilkelly, of the Bengal Army; Surgeon-Major George Edwin Seward, M.D., of the Bombay Army.

The following officers are granted a step of honorary rank on retirement:—Deputy Surgeon-General Richard Henry Perkins, of the Bengal Army, to be Surgeon-General. Brigade Surgeon Alexander Morison Dallas, of the Bengal Army, and Brigade Surgeon George Stewart Watson Ogg, of the Madras Army, to be Deputy Surgeons-General. Surgeon-Major Frederick William Alexander De Fabeck, of the Bengal Army, and Surgeon-Major Charles Robertson, of the Madras Army, to be Brigade Surgeons.

ENGINEER VOLUNTEERS.—2nd Gloucestershire (the Bristol): Arthur Frederick Blagg, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS.—2nd Volunteer Battalion, the Queen's Own (Royal West Kent Regiment): Surgeon Bertie Pardoe Matthews is granted the honorary rank of Surgeon-Major.—21st Middlesex (the Finsbury): Surgeon Francis Edward Thurland resigns his commission.—1st Cambridgeshire: Honorary Assistant-Surgeon William Groom resigns his commission.—1st Cornwall (Duke of Cornwall's): Richard Charles Mason Pooley, Gent., M.D., to be Surgeon; Edward Scudamore Angove, Gent., to be Acting Surgeon.—1st Dumfries: James Maclachlan, Gent., M.B., to be Acting Surgeon.

ARTILLERY VOLUNTEERS.—1st East Riding of Yorkshire: The services of Surgeon Henry Dodd are dispensed with.

MEDICAL NOTES IN PARLIAMENT.

Brigade Surgeons.

IN the House of Commons on Friday, November 21st, in reply to Sir H. Fletcher, the Marquis of Hartington stated that vacancies in the rank of brigade surgeon had not been filled up since the issue of the Circular on August 1st as to the examinations. The officers among the senior surgeons-major who had to be examined were serving in all parts of the world; and the promotions could not take place until all their examinations had been held and had been considered. But as the promotions would be antedated to the time when the vacancies severally occurred, the officers promoted would not be injured by the delay. The home examinations were fixed for the 27th and 28th inst., those for the colonies for December 1st, and in India as soon as arrangements could be made.

The Contagious Diseases Acts.

On Monday, Sir T. Brassey, in reply to Mr. Hopwood, stated that, as is well known, the police no longer exercise any compulsory powers in connexion with the Contagious Diseases Acts, but voluntary applicants are received into the lock hospitals on signing a form attested by an inspector of police. It had been suggested to the Mayor of Portsmouth that the duty of attestation should be performed by the superintendent of borough police on payment of a fee of 2s. 6d.; but this payment was proposed as a remuneration for the extra duty entailed on the superintendent, and not as an inducement to patients to enter the lock hospitals.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Primary or First Professional Examination for the Fellowship at meetings of the Board of Examiners on the 24th and 25th inst.:—

Farnell, Henry Dawson, University College.
Gilford, Hastings, Guy's.
Gregory, Alfred, London.
Harris, Clayton Campbell, St. Bartholomew's.
Lamont, John Charles, Edinburgh.
Owen, Samuel Walshe, Guy's.
Porter, Thomas Morrison, Liverpool and University College.
Taylor, William Frederick, Kingston and Guy's.
Taylor, Frederick Howard, London.
Williams, William, St. Mary's.

Of the 21 candidates examined 11 failed to satisfy the Board, and were referred for six months' further anatomical and physiological study.

COLLEGE OF PHYSICIANS IN IRELAND.—At the November examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Robert Abraham, John Martin Coates Cole, Eugene Crowley, Ignatius P. Doyle, John T. Gaynor, Daniel Kenny, Patrick Joseph Kiernan, Annie McCall, John McGuinness, James Lougheed Rowlett.

MIDWIFERY.—Robert Abraham, John Martin Coates Cole, Eugene Crowley, J. P. Doyle, Thomas Fagill, John T. Gaynor, Charles Hayden, Daniel Kenny, Patrick Joseph Kiernan, Marcus Moore Loudon, Matthew McAuley, Annie McCall, John McGuinness, James Lougheed Rowlett, Hugh Smith Morrison, William Alexander Wadsworth.

The undermentioned have been admitted members:—

Frederick Joshua Roberts. | Henry L. Smith.
Thomas Frederick Young.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Nov. 29th:—

Gregory, Edward Thomas, Charing-cross Hospital.
Lees, William, University College.
Loftus, Arthur Smith, Charing-cross Hospital.
Mullis, Geo. William, Guy's Hospital.
Orr, Joseph Orlando, Toronto University.
Shadwell, Harry Winstanley, St. Bartholomew's Hospital.
Thomas, Thos. W., University College.

The following gentleman also on the same day passed the Primary Professional Examination:—

Theodore Albert Vores Ford, St. Thomas's Hospital.

THE newly erected Lying-in Hospital at Brownlow-hill, Liverpool, was formally opened on the 19th inst.

PATHOLOGICAL SOCIETY.—Tea and coffee will in future be provided at the meetings of the Society from 8 to 9 P.M., instead of at the close of the meeting as heretofore.

THE Princess Christian has consented to open the new building in connexion with the Middlesex Hospital on Tuesday, Dec. 16th, at 12.30 P.M.

THE Dean and Chapter of Durham have agreed to grant an acre of land on Gilesgate Moor to the Durham Corporation as a site for a hospital for infectious diseases.

AN inspection of the Ambulance Station situated in Seagrave-road, Fulham, will be made by the managers of the Metropolitan Asylums Board on Saturday, the 29th inst., at 2.30 P.M.

HYDROPHOBIA has been rampant in Vienna for some weeks, there already having been some eighty cases and eleven deaths.

AN outbreak of diphtheria has occurred in the village of Littlebourne, near Canterbury, and it has been deemed advisable to close the schools.

SCARCITY of water is still being complained of by the inhabitants of Manchester and by the residents of many districts of Yorkshire.

THE Royal Hants County Hospital has received a donation of £500 from Mr. Thomas Courtney of Headbourne Worthy, and also, through him, of £100 from his sister, Miss Courtney.

PRESENTATION.—On the 4th inst. Dr. M. W. Taylor, late of Penrith, was presented by the inhabitants of the town and neighbourhood of Penrith with a service of silver plate and an address, on the occasion of his retirement from the town.

THE Rev. G. N. Godwin, Chaplain to the Forces, makes a public appeal to the benevolent on behalf of the wives and children of invalid soldiers at the Netley Hospital, who, he states, are sadly in need of warm clothing at this season of the year.

AT a meeting of the British Medical Temperance Association, held on Tuesday last in the Medical Society's Rooms, it was announced that the President, Dr. B. W. Richardson, F.R.S., and the Council were now prepared to offer a prize of 100 guineas for the best essay on the Physical and Moral Advantages of Total Abstinence from Intoxicating Liquors, to be competed for by medical students in the United Kingdom. Dr. Heywood Smith subsequently read a paper on the Use of Alcohol by Parturient Women.

UNIVERSITY OF CAMBRIDGE.—Dr. Donald MacAlister has been elected to the new examinership in medicine necessitated by the increasing entry for the Third M.B. Examination.—The following have been appointed members of special boards of studies:—Medicine: Mr. E. Carver, St. John's. Physics and Chemistry: Mr. P. T. Main, St. John's. Biology and Geology: Mr. J. W. Hicks, Sidney Sussex. The following gentlemen have been appointed members of the syndicate of State Medicine: Dr. Bradbury and Professor Dewar. At a congregation held on the 20th inst. the degree of Bachelor of Medicine was conferred on Oswald Auckinleck Browne, Trinity.—During the Michaelmas Term the examinations for Medical and Surgical degrees will be held as follows:—For the degree of Bachelor of Medicine, first examination, Dec. 2nd, 3rd, 4th, 5th, and 6th; second examinations, Dec. 5th, 6th, 8th, 9th, and 10th; third examination, first part, Dec. 9th and 12th; second part, Dec. 10th, 11th, 13th, 15th, and 16th. For the degree of Bachelor of Surgery, Dec. 12th and 13th. For the degree of Master of Surgery, Dec. 12th and 13th.

HOSPITALS FOR INFECTIOUS DISEASE.—The Works and Sanitary Committee of the Kensington Vestry having considered the special report of the General Purposes Committee of the Asylums Board upon the subject of the reception and treatment of non-pauper cases of infectious diseases at the marquee hospitals, reported on the 19th inst. that they saw no reason to depart from the principles already adopted by the vestry—viz., that the managers should be empowered to make adequate provision of hospital accommodation for infectious disease, for all classes of the population in need of such accommodation; that patients should be admitted into the managers' hospitals upon certificates signed by any duly qualified medical practitioner, conjointly with the order of the medical officer of health; that, as the hospitals of the managers have been established for the common good at the public cost, no compulsory payment should be exacted from persons whom the sanitary authority may deem it necessary or expedient to remove to the hospitals for the purpose of isolation; that all expenses incidental to the maintenance and treatment of such persons in the hospitals should be defrayed out of a common sanitary fund, the metropolis being treated for the purpose as a single district; and that steps should be taken to alter, by Act of Parliament, the constitution of the Board, by severing its connexion with pauperism in so far as relates to the treatment of infectious diseases, and by providing for the election of a certain proportion of the managers by the several sanitary authorities—i.e., the vestries and district boards.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ADAM, Mr. MATTHEW A., has been appointed Public Analyst for the County of Kent.

BROGDEN, R. W., M.R.C.S., L.R.C.P., has been appointed House-Physician to Guy's Hospital.

BURROUGHS, JOHN E. B., M.R.C.S., L.S.A.Lond., has been appointed by the Court of Assistants of the Merchant Taylor's Company Medical Attendant at the Company's and at Christopher Boone's Almshouses, at Lee, Kent, in succession to the late Mr. C. W. Steel.

CAIGER, F. FOORD, M.B., B.S., M.R.C.S., L.R.C.P., has been appointed House-Physician to St. Thomas's Hospital.

COOMBS, W. GODWIN, M.D., has been appointed Resident Medical Superintendent of the Eastern Counties Asylum for Idiots, Colchester.

DUNLOP, ROBERT S., M.B., C.M.Ed., has been appointed Medical Officer to Kilmaurs Parochial Board, vice G. Buchan, M.B., resigned.

FIELDEN, W. E., M.B.Lond., has been appointed Assistant Medical Officer to the Asylum for Idiots, Earlswood, Redhill, Surrey, vice B. Hall, M.B.Lond., resigned.

GREEN, C. D., M.B., M.R.C.S., L.R.C.P., has been appointed Resident Accoucheur to St. Thomas's Hospital.

HEATON, FRED. LUXMOORE, M.B.Oxon., L.K.Q.C.P.I., M.R.C.S., has been appointed Medical Officer for St. Asaph District and Workhouse, St. Asaph Union, vice Lodge.

HICK, JOE, M.R.C.S., L.R.C.P. & L.M.Ed., late Senior Assistant House-Surgeon to the General Infirmary at Leeds, has been appointed Junior Resident Medical Officer to the Leeds Public Dispensary.

JOHNSTON, G. D., M.R.C.S., L.R.C.P., has been appointed House-Physician to St. Thomas's Hospital.

JONES, WILLIAM WANSBROUGH, M.A., M.B.Oxon., B.Sc.Lond., M.R.C.S., has been appointed Resident Medical Officer of the Convalescent Hospital of the Manchester Royal Infirmary, Cheadle.

KENNA, M. F., L.R.C.S.I., L.R.C.P.E., &c., has been appointed Medical Officer to the Fontstown Dispensary District of the Athy Union, co Kildare, Ireland.

LANKESTER, H. H., M.R.C.S., L.S.A.Lond., has been appointed Non-Resident House-Physician to St. Thomas's Hospital.

LAWSON, R., M.R.C.S., L.S.A.Lond., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

MACKENZIE, H. W. G., M.A., M.B., has been appointed Assistant House-Physician to St. Thomas's Hospital.

MARRINER, W. H. LISTER, M.B., M.R.C.S., L.R.C.P., has been appointed Clinical Assistant in the Department for Diseases of the Throat at St. Thomas's Hospital.

MURCHISON, FIN. FIN., M.B., M.A., has been appointed Medical Superintendent of Peckham House Asylum, Peckham, S.E., vice J. Asbell Brown, M.R.C.S., L.S.A.Lond., resigned.

OAKES, HENRY, L.R.C.P.Ed., L.F.P.S.Glasg., has been appointed Medical Officer for the Loppington District of the Wem Union, vice Wilson.

ORFORD, J., M.R.C.S., L.R.C.P., L.S.A.Lond., has been appointed House-Surgeon to St. Thomas's Hospital.

PARKINSON, SIDNEY GEORGE, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Second District of the Wimborne and Cranborne Union, vice Wyke-Smith.

PLOWMAN, S., M.R.C.S., L.S.A.Lond., has been appointed Clinical Assistant in the Department for Diseases of the Skin and Ear at St. Thomas's Hospital.

ROBINSON, H. B., M.R.C.S., L.R.C.P., has been appointed House-Surgeon to St. Thomas's Hospital.

SALVAGE, J. V., M.S., M.B.Dur., M.R.C.S., L.R.C.P., has been appointed House-Surgeon to Guy's Hospital.

STOWERS, J. HERBERT, M.D., has been appointed Physician to the Department for Skin Diseases, North-West London Hospital.

SUTTON, S. W., M.D., B.S., M.R.C.S., L.R.C.P., has been appointed Ophthalmic Clinical Assistant to St. Thomas's Hospital.

WHITE, E. WOOD, B.A., M.B., B.Ch. Univ. Dub., has been appointed Honorary Surgeon to the Birmingham and Midland Eye Hospital, vice Edwin Cheshire, F.R.C.S., resigned.

MARRIAGE.

CARTER—BAKER.—On the 20th inst., at St. Jude's, South Kensington, Sidney Herbert Carter, M.B., Army Medical Staff, youngest son of the Rev. Henry Carter, D.D., of Kingstown, late Rector of Ballintoy, co. Antrim, to Henrietta Margaret, youngest daughter of the late Rev. Robert Duncan Baker, M.A., Vicar of Friston and Snape, Saxmundham, Suffolk, and of Mrs. Duncan Baker, of Hogarth-road, Cromwell-road, S.W.

DEATHS.

BODDY.—On the 20th inst., at Camberwell-road, William Barnard Boddy, M.R.C.S., aged 89.

FLUDER.—On the 15th inst., at Cromer, Norfolk, Arthur Riedell Fluder, M.R.C.S., L.S.A.Lond., youngest son of the late Charles Fluder, of Lymington, Hampshire, aged 40.

MAHOMED.—On the 22nd inst., at Manchester-square, W., Frederick Akbar Mahomed, M.B.Cantab., F.R.C.P., Assistant-Physician to Guy's Hospital, in his 36th year.

MATURIN.—On the 19th inst., of scarlet fever, Leslie Maturin, M.K.Q.C.P.I., Resident Physician at Cork-street Fever Hospital, Dublin, eldest son of John Maturin, Esq., of Newtownstewart, co. Tyrone, aged 25.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, December 1.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations 10½ A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M
LONDON HOSPITAL MEDICAL COLLEGE.—3 P.M. Mr. Jonathan Hutchinson: Head Injuries, Hernia, and other Matters.
ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.
MEDICAL SOCIETY OF LONDON.—Mr. Boyce Barrow: A Case of Gastrostomy (with Specimen).—Mr. John H. Morgan: Cyst of the Neck.
ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Casual Communications by Messrs. J. C. McAdam, Storer Bennett, W. Coffin, and Dr. St. George Elliott.—Mr. J. Bland Sutton: Comparative Dental Pathology.

Tuesday, December 2.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Pye-Smith: Cystic Disease of Cerebellum, Kidney, and Pancreas.—Dr. Lanchester: Intussusception in an Adult Male.—Dr. Carrington: (1) Simple Ulceration between the Trachea and Œsophagus. (2) Atrophy of the Liver (card).—Mr. Treves: (1) Two Specimens of Tumour of Soft Palate. (2) Epithelioma of Bladder, with Renal Calculus (card).—Mr. Eve: Lympho-Sarcoma of the Bladder.—Mr. Poland: Congenital Hydrocele of the Spermatic Cord.—Mr. Bowlby: (1) Fistular Communication between the Bladder and the Rectum (card). (2) Infiltrating Fibroma of Thyroid.—Dr. Paddison: A Case of Charcot's Disease, with Sections of the Spinal Cord (card).—Mr. Hudson will show a new and simple Ether Microtome.

Wednesday, December 3.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays, at 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.—Skin Department: 9.30 A.M., on Tuesdays and Fridays.
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations 2½ P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
LONDON HOSPITAL MEDICAL COLLEGE.—3 P.M. Mr. Jonathan Hutchinson: Dislocations and Fractures.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Horrocks, Dr. Carter, and others.—Adjourned Discussion on Dr. Graily Hewitt's paper on "The Severe, or so-called 'Uncontrollable,' Vomiting of Pregnancy;" to be opened by Dr. Robert Barnes, and followed by Dr. Braxton Hicks.—Dr. Potter: A Case of Retained Product of Conception.—Dr. McKeown: The Prevention of Ophthalmia Neonatorum and its Ravages.

Thursday, December 4.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.
NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Mr. W. S. Savory: The Pathology of Cancer. (Bradshawe Lecture.)
HARVEIAN SOCIETY.—8.30 P.M. Mr. Thomas Bryant: The Mode of Death in Acute Intestinal Strangulation and Chronic Intestinal Obstruction. (Harveian Lecture.)

Friday, December 5.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Pathological Specimens by Mr. Percy Dunn. Clinical Cases by Mr. Keetley.—Mr. Spencer Watson: Sympathetic Ophthalmia.—Mr. B. F. Benham: The Uses of Sulphide of Calcium.—Dr. Thudichum: Inflammation, Abscess, and New Growths of Echmoid Cells.

Saturday, December 6.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

SUPPOSED CANCER OF THE RECTUM IN A BOY AGED NINETEEN.

To the Editor of THE LANCET.

SIR,—If you think the following description of a case of supposed cancer of the rectum in a boy of only nineteen years of age worthy of record, I should feel obliged by its insertion in your valuable journal, as the facts are peculiar and interesting.

I was called on Sept. 27th into the country to visit the case in question in consultation with the medical attendant. I was informed that the patient was suffering from cancer of the rectum. The patient had always been in perfect health, a fine, well-grown, muscular lad, but had had dysentery for several weeks, which had not been controlled by treatment. A week previous to my visit a tumour was found occupying a portion of the rectum posteriorly, which the medical attendant in conjunction with another practitioner pronounced to be cancer of the rectum. I found the boy free from any sign or symptom of cancer of the rectum. Upon examination, there was undoubtedly a tumour; it was of a rounded nature, well defined, and resembling to the feel the os of the gravid uterus—not unlike the thumb and knuckle flexed. There was frequently also considerable hæmorrhage of a very dark colour, which I suggested was from the bowels. The patient was fairly nourished and in good spirits. There was no characteristic cachexia, no pain, and no constipation or obstruction; but the hæmorrhage was evidently having effect upon the strong constitution of the boy, and, if unchecked, would most probably be fatal. I was inclined to give the patient the benefit of the doubt; nevertheless, the medical attendant strongly insisted that the case was one of cancer of the rectum. I believe a case of cancer of the rectum in one so young is not on record; and this was admitted.

I should feel obliged if any of my medical brethren would state their view as to the case.

I am, Sir, yours truly,

London, Oct. 8th, 1884. D. M. DOUGLAS.

Dr. G. H. Simmons (Lincoln, Nebraska).—We are unable at present to devote space to the subject.

"IRRITATION OF THE SKIN FOLLOWING THE APPLICATION OF VASELINE AS A SURGICAL DRESSING."

To the Editor of THE LANCET.

SIR,—Referring to our letter of the 17th inst. on the subject of the use of vaseline in the Leeds Infirmary, we fear that we used language which may be misinterpreted to mean that the red vaseline was not fit for human use. We had no such intention, and should certainly not have been a party to the sale to any infirmary or hospital of goods which it would be injurious to use. The higher grade of vaseline is that which we sell for use in hospitals throughout the country, the principal demand for the red or inferior grade being for veterinary use; but the latter would be in no manner unfit for hospital use, although necessarily inferior to that which is more highly refined.

We are, Sir, yours faithfully,

CHESEBROUGH MANUFACTURING COMPANY.

Holborn-viaduct, E.C., Nov. 26th, 1884.

THE ARCHÆOLOGY OF HYGIENE.

THERE is no denying that Pagan Rome was superior to Pontifical in the observance of sanitary laws—so much so, indeed, that the historian of public health might write an instructive chapter on the contrast. To say nothing of the modern neglect of personal ablution, as compared with the attention betowed on it even under the Republic, let alone the Empire, the disposal of animal refuse seems to have engaged in the century before Christ an amount of civic care which the Rome even of twenty-five years ago might have imitated with advantage. Excavations recently in progress on the margins of the Viminal and Esquiline hills have brought to light inscriptions bearing upon the sanitary regulations of that period, one of them referring to the guardianship and the limits imposed on an extensive dung field in the Campus Viminalis. The urban prætor at whose instance the edicts in question were inscribed was Lucius Sentius, who belonged to an illustrious Volscian family of the "Atina Potens" of Virgil. The inscription concludes with the following sanitary admonition:—

STERCVS LONGE
AVFER
NE MALVM HABEAS.

That is: "Remove ordure to a great distance, as you would avoid evil consequences." It has taken well nigh fifteen hundred years to revive and give practical force to this edict of the Pagan Republic!

Idem.—There is no invariable rule. The custom of the place must decide the matter.

Mr. McGill's paper will be published in an early number.

"THE LIBRARY OF THE COLLEGE OF SURGEONS."

To the Editor of THE LANCET.

SIR,—I was very glad to see in your issue of the 15th inst. the letter of "A Member," referring to the above library.

In June, 1883, I wrote to the Secretary, calling his attention to the short time during which the library was open, and the many interruptions that were caused to readers through the room being frequently closed for examination purposes. The reply I received somewhat surprised me; for while the interruptions were held to be unavoidable, owing to there being no other room large enough for the examinations, no increase in the time during which the library is opened could be granted, as it would hardly be fair to the officials to ask them to prolong their hours so as to accommodate a certain number of readers. Luckily for the credit of the College, this view was not held by the Library Committee, before whom the subject was brought a few months later; for they decided to open the library one hour longer—viz., from 11 A.M. to 6 P.M., instead of from 11 A.M. to 5 P.M.

Now that the subject of library accommodation is being brought forward, and Sir Spencer Wells holds out hopes that something will be done, it seems to me to be an opportune time to call attention to one great disadvantage under which medical men in London work. So far as I am aware, there is no complete library in the metropolis from which books can be borrowed for reference at home, with the exception of that of the Medical and Chirurgical Society, whose high entrance fee and subscription, to say nothing of other hindrances to entrance, are prohibitive to most medical men. In Manchester books can be borrowed from the Medical Society's library; in Strasburg and Dorpat, and no doubt many other continental towns, from the University library. But here there is nothing of the kind. Surely, it is time that something was done.

I am, Sir, yours truly,

Somerfield-road, N., Nov. 24th, 1884. R. W. GREENISH, F.R.C.S.

"IS DEAFNESS A BARRIER TO PRACTICE?"

To the Editor of THE LANCET.

SIR,—In your issue of Aug. 16th I noticed a letter signed "Constant Reader," asking the opinion of any medical man as to the prospects of continuing to practise when afflicted with deafness. Unfortunately I am one who can sympathise with your correspondent in his affliction; and though my letter will reach you some months after the date of the publication of his, the relation of my experience may be of service, and, if so, of some comfort. For five years I practised in the country in this colony, during which time I was very deaf, and had to use an ear trumpet. To this my patients took very kindly indeed, and I made about £800 a year. Last year I had further ear mischief, which completely destroyed one ear; but I found that with an ordinary speaking-tube I could hear almost the lowest whisper—in fact, I heard much better than I did with the trumpet before the right ear was destroyed. Without the tube I am almost absolutely deaf. On this last ear trouble happening, little hope was given of my ultimate recovery. I therefore left the country, settled in the city as a chemist, and practised with the aid of a tube, all the doctors advising me that it would not be unprofessional to do so under the circumstances. Now I have a moderate practice, and it astonishes me how naturally everyone takes to speaking through the tube. My practice, of course, is not large; but, with the chemist's shop worked by assistants, I make sufficient to support myself and family fairly well. If "Constant Reader" will boldly make use of a speaking-tube as a matter of course, with a polite notification that he can thus hear better, I am sure he will find very few express astonishment, and he will also find they will retain confidence.

I am, Sir, yours truly,

New South Wales, Sept. 26th, 1884. MEDICUS.

"THE WANT OF PRACTICAL TEACHING IN MIDWIFERY."

REFERRING to a letter which appeared in our last week's number from a "Member Brit. Med. Assoc.," "Another Member" writes:—

"A charge has been made against the Dublin medical schools which is not at all borne out by facts. I have always heard that the Dublin men had the reputation of being well grounded in midwifery. In my time (eleven years ago) the teaching in the Coombe Lying-in Hospital was of the most thorough character, professors and students being very enthusiastic in their work, and the drilling of the latter being of the most practical kind. As to the Rotunda Hospital, Dr. Playfair, in his work on Obstetrics, states: 'It may be fairly assumed that the practice of the distinguished heads of that well-known school represents the most advanced and scientific opinion of the day.' But if the teaching there be as defective as your correspondent tries to make out, how can he account for the feeling so prevalent among English senior students of the present time that obstetrics can be learned nowhere so well as in Dublin? Or how is it that they flock over there in such numbers, each cherishing the conviction that he is going to the fountain-head of obstetric science, as others go to Germany to perfect themselves in ophthalmology and pathology?"

"The X.P." remarks on the same subject:—

"The experiences a 'Member Brit. Med. Assoc.' has of my countrymen's knowledge of midwifery are, as far as I know, unique. Why this selection of Irishmen as synonyms for ignorance of midwifery while other countries send in their representatives? No recently qualified man is expected to be a Spencer Wells. Proficiency in obstetric craft is the result of 'experience and wisdom,' as Professor Macnamara puts it; but every medical man should know how to feel the os. No such ignorance is justifiable. And though students do not study the book of nature as they ought to, I refuse to believe that the Irish schools send out ignorant medical men as a rule, and I deby *in toto* their incompetency in midwifery. It is, indeed, a pity that Irish graduates should be made the subjects, in my opinion unjustly, of uncalled-for censure. They have to contend with the greatest difficulties that blind and guilty prejudice can subject them to, as the medical agents in London and elsewhere can testify."

"Dublin" remarks:—

"As to the Dublin schools 'turning out' men deficient in practical knowledge, is it not the case with every school, English as well as Irish, probably owing to the difficulty of ascertaining the practical knowledge of the student. 'Member Brit. Med. Assoc.' has shown up Dublin men rather to a disadvantage, but I can inform him that I have met highly qualified men (not Irish) who could not tell when labour had commenced, and on one occasion I was sent for and requested to bring long forceps to assist in delivering a case in which the short forceps were of no use. On examination I found a breech presentation. Yet this medical man was highly qualified, had a pocketful of diplomas (M.D., &c.), and was not an Irishman. Your correspondent will therefore see that it is not only Irishmen who are armed with diplomas to kill and cure."

Mr. Soutter.—We are receiving copies of the disgraceful pamphlet every week. The name of the author has been removed from the roll of the London College.

Ethical.—The title suggested by our correspondent is right.

HIGH DEATH-RATE IN CARDIFF.

To the Editor of THE LANCET.

SIR,—I think you would be doing a good work if you called attention to the high rate of mortality in this town.

Two years (or even less) ago we were boasting of the very low death-rate we had as compared with other large towns; but now that is all changed, and at the present time there are only three towns (Liverpool, Bolton, and Preston) which record for the quarter ending Sept. 29th, 1884, a higher death-rate than our own. If the Registrar-General's Return be examined, it will be found that in the quarter just mentioned deaths from the following zymotic diseases took place in Cardiff:—small-pox, 2; measles, 1; scarlet fever, 55; diphtheria, 7; whooping-cough, 3; fever, 9; diarrhœa, 100. Now, it will naturally be asked, What are the causes producing this high rate of mortality? I believe myself that the following conditions contributed largely to swell the death-rate: 1. The foul state of the main sewers, which gave rise to the most offensive exhalations from the "open" gratings in the streets. 2. The scarcity of water. 3. The insanitary condition of the new houses. In the majority of cases these are built without foundations, and with mortar which is composed of house refuse and lime. Then there is no supply of water to the closets. The pans are flushed (?) by pouring water down. I am sure this is the worst system. Then the soil pipes are hardly ever ventilated. 4. Houses are allowed to be occupied long before they are fit for occupation. 5. Overcrowding of houses. In consequence of the high rents two or three families are compelled to live in a house only large enough for one family.

The death-rate as given by the medical officer of health for the thirteen weeks ending Aug. 23rd, 1884, is even larger than that given by the Registrar-General in the third quarter of the present year. Dr. Paine gives the death rate as 28·8 per 1000, and the deaths from the seven zymotic diseases as 66, being at the rate of 9·1 per 1000, as against 6·5, the death-rate of the other large towns.—I am, Sir, yours truly,

Cardiff, Nov. 9th, 1884. T. GARRETT HORDER.

J. R. F. (Glasgow).—As in all eruptive fevers, the invasion of dengue is beset with difficulties in diagnosing it from the early stage of allied febrile maladies. There is a useful treatise on Dengue by Dr. Gerson da Cunha (Thacker and Co., Bombay and London, 1872), who had specially favourable opportunities of studying it during the epidemic which prevailed in Bombay in 1871-2.

Mr. J. A. Shaw.—The letter has been forwarded.

"M.B. PASS EXAMINATION, UNIVERSITY OF LONDON."

To the Editor of THE LANCET.

SIR,—As you have allowed several letters to appear on this subject, perhaps you will spare me a few lines.

The unfairness of a question on "unilateral hæmatokolpos" has been adverted to; but probably few of your readers are aware of the serious difference which the total omission of one question may make to a candidate. The "pluck" this year is larger than usual—a result doubtless due to the selection of this question. Then, too, besides the rarity of the affection, the term employed to define it is open to objection. A university which ignores Greek ought not to allow its examiners to set a question which can only be answered by knowing the meaning of the Greek word "kolpos." The parenthetic explanation (retention of menses) given in the paper does not precisely locate the affection.

A general complaint amongst candidates is the scanty time allowed for the papers, or, rather, the length of the latter, especially those set by the examiners in medicine. I enclose copies of those recently given, and beg respectfully to challenge either of the examiners to answer them fully within the time allowed. I do not mean as a test of knowledge, but as a test of rapid writing. I do not doubt the knowledge of either of these gentlemen, but I do question very much their capability of putting it on paper in the short time allowed. I also enclose an analysis of the pass-list, which furnishes another proof, were any needed, of the justice of the remarks frequently made in your editorial columns as to the inaccessibility of London degrees to London students. Only thirty-one London students have now graduated, unless we include the two female candidates. Our largest school only graduates four students. At the same school the number of new entries last October was 125.

I am, Sir, yours truly,

Nov. 24th, 1884. ONE WHO HOPES FOR REFORM.

M.B. PASS EXAMINATION.—1884.

Monday, Nov. 3rd. Afternoon, 3 to 6.

General Pathology, General Therapeutics, and Hygiene.

Examiners: W. H. Broadbent, Esq., M.D., and W. M. Ord, Esq., M.D.

1. Enumerate the various sources of lead-poisoning, and discuss, particularly in relation to manufacturing processes, the means of prevention.

2. Discuss the various means and methods available for the treatment of insomnia.

3. Describe the local morbid processes resulting from pyæmia. [N.B.—The causation of pyæmia is not included in the question.]

4. What are the conditions of soil and climate which give rise to intermittent and remittent fevers? What precautions should be taken by people resident in or travelling through malarious districts?

5. Enumerate and classify the objects to be gained by the administration of aperients, specifying the particular drugs to be selected for particular purposes.

6. Give the etiology and pathology of purpura.

Tuesday, Nov. 4th. Afternoon, 3 to 6.

Medicine.

Examiners: W. H. Broadbent, Esq., M.D., and W. M. Ord, Esq., M.D.

1. Specify the causes of over-distension of the right side of the heart. Describe the symptoms to which this condition may give rise, and the treatment to be employed for its relief.

2. Describe an attack of measles, with the complications which may arise in the course of the disease, and the treatment to be adopted under different circumstances. In what respects do German measles differ from common measles?

3. Describe the morbid changes which may result in diminution of the size of the liver, the appearances presented by that organ in each form of disease, and the signs and symptoms by which the several affections may be recognised during life.

4. Describe the several varieties of erythema. Discuss their causes and treatment.

5. Describe the symptoms, course, and differential diagnosis of progressive muscular atrophy.

6. What forms of suppuration may occur in connexion with the kidneys? Give the pathology, symptoms, and diagnosis of one of them.

SIAMESE THEORY AND PRACTICE OF MEDICINE.

DR. E. A. STURGE gives in a recent number of the Philadelphia *Medical Times* an interesting account of this subject. All nature, according to the Siamese, is composed of four elements—viz., earth, water, fire, and wind. The human body is supposed to be made up of these same elements, which are divided into two classes, visible and invisible. To the former belongs everything that can be seen, as the bones, flesh, blood, &c.; to the latter the wind and the fire. The body is composed of twenty kinds of earth, twelve kinds of water, six kinds of wind, and four kinds of fire. The Siamese divide the body into thirty-two parts, as the skin, heart, lungs, &c. The body is thought to be subject to ninety-six diseases, due to disarrangement of the earth, wind, fire and water. An undue proportion of fire causes fevers, and dropsies are caused by too great a proportion of water. Earth is supposed to produce disease by invisible and impalpable mists and vapours, and wind can cause all manner of complaints. The natives use almost everything as medicine; the bones and skins of various animals occupy a large part of their pharmacopœia, while the galls of snakes, tigers, lizards, &c., are among the most valuable of their medicines. Burnt human bones, powdered and mixed with an equal portion of powdered alum, form a favourite medicine for sprinkling on ulcers. The eye-teeth of tigers, bears, lions, and various other animals (the more the better), ground up together, form the most popular remedy for fevers. The ashes of earthworms and human hair, mixed with cocoanut-oil, are frequently used for cuts. Dissection is never practised among the Siamese, consequently they are grossly ignorant in regard to the science of anatomy. The functions of the different organs are not at all understood. In the heart is supposed to be a cavity about the size of an almond. This cavity is thought to be filled with a fluid which changes its colour and consistency with our passions. When we are calm and peaceful, this fluid is perfectly clear, like water; when we are angry, it is turbid; when very angry, it turns dark; and when we are in love, it is red. In stupid persons the apex of the heart is rounded, while in those possessing the usual amount of wisdom it is pointed. It is not known that the heart has anything to do with the circulation.

Omega.—The Health Crape may be obtained of H. Ammam, 2, Star-court, Broad-street, E.C., or of Howell and Co., 60, Watling-street.

DEATHS FROM INANITION.

To the Editor of THE LANCET.

SIR,—May I be allowed to make one or two more so-called "causes" of death that ought not to be returned in medical certificates, and certainly ought not to be accepted by the registrars. First, concerning "inanition." It is, as you remark in an annotation in your issue of Nov. 1st, a condition of actual or partial starvation, which may be induced by wilful deprivation of proper food, or by the inability of the patient to digest any food in consequence of disease of some kind. In either of such cases the primary cause should be stated when death is the result. Again, "convulsions," being a symptom of some remoter ailment, cannot be a cause of death. Convulsive seizures may be the result of any one of various causes, which should be inquired into, and the actual cause stated in a certificate of death. Once more, "Death from natural causes" is a common verdict by coroners' juries, and a certificate is generally given by the medical witness (who has attended the case), in accordance with his own testimony at the inquest. If some of these cases were more searchingly investigated, it would be found that, instead of the death being "natural," especially in the case of little children, the fatal result is too often brought about by gross neglect or culpable carelessness, which all humane individuals must regard as an *unnatural* cause.

The mortality statistics would be far more valuable, because more true and trustworthy, if all vague certificates as to causes of death, such as those indicated above, were henceforth rejected by the Registrar-General, who should demand more precise definitions from medical practitioners and all others concerned.—I am, Sir, yours obediently,

Nov. 11th, 1884. M. A. B.

"A NEW-BORN INFANT OF EXTRAORDINARY SIZE."

To the Editor of THE LANCET.

SIR,—Mr. George Eddowes records the birth of a boy weighing 20 lb. 2 oz. This is so uncommon that more details would be interesting. I was under the impression that a child delivered by Mr. Owen at the Queen Charlotte Lying-in Hospital when I was house-surgeon there, weighing 17 lb., was about the largest on record. But this is now greatly out-scaled. The following details should be stated: Is the child alive? Have its parents had other children? If so, what did they weigh? Is the period of gestation established—that is, was the gestation presumed to be protracted? What is the occupation, mode of life, age, and diet of the parents? Was the child delivered by Mid. of fet, or was delivery spontaneous? Did the mother suffer any laceration during labour? In this wonderful case nature seems to have made a little mistake. The weight of the puppily distributed, would have made very respectable triplets.—I am, Sir, yours truly,

ROBERT BARNES.

COCAINE IN DENTAL OPERATIONS.

IN reply to correspondents, we may say that we hope in the course of a week or two to be able to publish the results of experiments performed to determine the use of "cocaine" in dental operations.

THE WATER SUPPLY OF ROME.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 11th, page 665, your "own correspondent" at Rome seems to have very peculiar ideas on the subject of good drinking water. He vaunts that of the "Eternal City" as being "long known for purity as the finest in Christendom," which is saying a good deal to start with; and as having been again examined "with invariably satisfactory results," the said results showing the water to contain *only* 50 grammes per 100 litres of residue [or 50 parts per 100,000 of water], of which 50 grammes only 30 were carbonate *of lime* (I suppose he means), and 4 grammes magnesia.

Perhaps it is natural for foreigners to ignore things in the country they call "the States"; but the writer of the Roman letter must forgive me for saying that he will find it difficult to obtain authority for calling such water "pure," and *a fortiori* for calling it the "purest in Christendom." In benighted America we should call such water unfit for drinking, unless our object was the speediest possible creation of calculi. May I therefore add the analysis of the Brooklyn water, furnished this city for many years, of equal and unvarying purity.

Analysis.

Ammonia	Free	0·00075 gramme per 100 litres.
	Albuminoid	0·00826 " " "
Oxygen required to oxidise the organic matter		0·413 gramme " "
Nitrites		None.
Nitrates		1 gramme per 100 litres.
Chlorine		0·55 " " "
Total solids		6 grammes " "
Mineral solids		5 " " "
Organic and volatile solids		1 " " "

Hence we see (1) that the "free" ammonia is only one-eleventh of that deemed permissible in good water; (2) that the albuminoid ammonia is only half the permissible amount; (3) that the ratio of organic and volatile residue to mineral residue is very small, only 1 to 5; and (4) that if no better city water is presented—and I think Glasgow only excels us—the "Ridgewood water of Brooklyn" will "wear the bell" as "the purest in Christendom."—I am, Sir, yours truly,

NELSON B. DE S. SIZER, Bac.Sc., M.D.
(Neo-Eboracensis.)

Brooklyn, Oct. 27th, 1884.

Sigma should consult his partner as to the rule of the place in the matter. Forms of thermometer chart are legion; the simpler the better.

IS THIS OVER-PRESSURE?

To the Editor of THE LANCET.

SIR,—I should like to ask those who differ from Dr. Crichton Browne their opinion, as medical men, of the following questions, which were put to boys in Standards 6 and 7 at one of the Board schools in this neighbourhood—that is, to boys of the ages of thirteen and fourteen years:—"Describe the three sorts of levers, and give examples of each in the human body." "Describe 'fibrin' and 'liquor sanguinis.'" "Name all the involuntary muscles in the body, and state why they are so." I cannot vouch for the exact wording of the questions, as they were given me by a teacher from memory; but the above gives the intent and meaning of the questions.—I am, Sir, yours truly,

Holloway-road, N., Nov. 17th, 1884. W. HENRY KESTEVEN.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Harkin, Belfast; Dr. Saundby, Birmingham; Dr. Haughton, Norwood; Mr. C. Mann, Glasgow; Mr. St. G. Mivart, London; Mr. J. H. Clinical Lectures on CASES OF DIFFICULT DIAGNOSIS.

By SAMUEL FENWICK, M.D., F.R.C.P.L.,
PHYSICIAN TO THE LONDON HOSPITAL.

PERFORATION OF THE APPENDIX VERMIFORMIS.

WHEN a student first enters on his hospital career he is struck with the vast variety of cases presented to him. The diseases and their modifications seem to him so innumerable, the symptoms of many of them appear so closely to resemble each other, and the distinctions he is taught to regard as important for their discrimination are often in his view so trifling, that he despairs at ever being able to overcome the difficulties connected with their diagnosis. Experience, however, soon shows him that many of the maladies he encounters are readily recognised, and that the similarity of their symptoms is generally more apparent than real, and careful attention to the rules laid down for his guidance will usually enable him to arrive at a tolerably correct opinion as to the nature of most of the ordinary cases presented to his notice. But there are some affections that occur so rarely that only a few instances fall within the observation of any practitioner, and they are consequently apt to be overlooked or confounded with other maladies of more frequent occurrence, whilst the rules for their detection and treatment are necessarily vague or imperfect. It is some disorders of this kind that I would from time to time invite you to study with me, examining the symptoms they have presented during life, and, in such as have proved fatal, the morbid conditions discovered after death.

I propose that we should first consider some of the more obscure diseases of the abdominal cavity, inasmuch as, on account of the great number of organs, differing in structure, in size, and in functions, that are enclosed in it, the diagnosis of the more rare maladies is more difficult in this than in the other cavities of the human body; and also because increased certainty of diagnosis is likely to lead to improvements in treatment. The remarkable success that has of late years attended the operation of ovariotomy encourages the belief that if our diagnosis could be made more certain, some of the diseases now rebellious to medicine might be relieved by surgical procedures; for there can be no doubt that many of the operations performed prove unsuccessful not so much from the nature of the malady or from any special liability of the injured structures to secondary inflammation, as from the late period at which they are undertaken.

I would first invite your attention to a disease of rare occurrence, which has only of late years attracted the attention of practitioners, and which often presents considerable difficulty in diagnosis—viz., perforation of the vermiform appendage. Five cases of this kind have been admitted into the hospital during the past twelve months, and I have selected two that occurred in my wards as illustrations of the symptoms and course usually presented by the malady.

CASE 1.—A man, seventeen years of age, was admitted under my care on Feb. 14th, 1884, complaining of great pain in the abdomen, accompanied by weakness, to such an extent he was scarcely able to stand. He was very thin, with a face expressive of severe suffering, the eyes were sunken, and the skin remarkably dark around them. He referred the pain chiefly to the epigastric region, although it extended over the entire abdomen, which was tender upon the slightest pressure; he had frequent vomiting, and the bowels had been constipated during the whole period of his illness. The pulse was 108, very compressible; tongue much furred; respiration 42; temperature 99·8°. The abdomen was greatly distended and tympanitic, but the loins and flanks were not distended, and there were no visible movements of the intestines. The hypogastric region was dull on percussion; over the cæcum the note was less dull, and percussion upon this part gave rise to a gurgling sound. On examination by the rectum a mass could be discovered in front, which was smooth, and gave the impression of its consisting of several coils of intestine united together. He stated that he had always enjoyed good health until nine weeks ago, when he thought he had hurt himself by lifting a heavy roll of paper; since that time he had lost flesh, but had been free from pain, or any other symptom. Seven days ago he was suddenly attacked with severe pain of the epigastrium shortly after supper, and the pain had continued ever since, in spite of medical treatment. Perforation of the appendix was diagnosed, and he was ordered frequent and full doses of opium. During the next three days he seemed somewhat easier, the vomiting was less frequent, and the abdomen became less distended. The temperature sank on the second day to the normal point, and on the two subsequent days it was 97° and 97·6°. The physical signs remained unaltered, excepting that there was more fulness over the region of the cæcum, but the pulse became gradually more feeble, and he died on the tenth day of his illness.

Post-mortem examination.—A considerable quantity of pus escaped when the abdomen was laid open, and the intestines were seen to be everywhere adherent to each other, pus being situated between the adjacent coils. The part where the gurgling had been elicited by percussion was occupied by a fold of small intestine, bent upon itself, filled with air and fluid, and lying upon the cæcum, whilst the tumour felt through the rectum proved to consist of some coils of intestine united together and enclosing collections of pus, and adhering by recent lymph to the back of the bladder and the sides of the pelvis. There was also a considerable quantity of free pus in the pelvis. The appendix was extremely congested, the tip being of a purplish colour and much thickened; its sides at the lower third were covered with pus and lymph, and a concretion was felt impacted in its upper third, whilst between this and the tip was an ulcerated opening. The cæcum itself was congested, and contained only a few small pieces of fæces and bits of gelatinous-looking matter.

CASE 2.—A man, aged fifty, was admitted complaining of pain in the chest and abdomen. He was emaciated, sat upright in bed without any drawing up of the legs, and stated that the pain from which he suffered was not severe; the tongue was furred, there was no vomiting but frequent hiccough, the bowels were greatly relaxed, and he was unable to swallow solid food; the pulse was not much quickened, and his temperature was only 97·5°. Although so little complaint was made of pain, the hypogastrium was tender on pressure and slightly swollen, it was comparatively dull on percussion, and percussion over the right iliac fossa elicited a gurgling sound, as of air and fluid. He made no complaint of cough or expectoration, but there was dulness on percussion over the right supra-spinous fossa along with tubular respiration and increased tactile fremitus above and below the right clavicle. He had been a soldier and served in the Crimea and East Indies, and had formerly suffered from dysentery. Six months ago he first had pains of the chest and abdomen which had been at times so severe that he was unable to follow his employment of a labourer. He could not fix any time when the pain of the abdomen became worse, but five days before his admission he suffered from constant vomiting, which gradually subsided. During his residence in the hospital he never complained of much pain, but suffered greatly from diarrhœa, the bowels being relaxed as often as ten or twelve times in the twenty-four hours. His temperature was below the normal point, excepting on one occasion, when it reached 99°. He gradually died from exhaustion seven days after his admission, the physical signs remaining unaltered.

Post-mortem examination.—There was fibroid consolidation at the apex of each lung. On the right side was a cavity, and the middle and lower lobes of each lung contained tubercles; but there were no tubercles on the peritoneum and no ulceration of the small intestines or the cæcum. The small intestines were adherent to each other in the hypogastric region, with pus situated between the adjoining coils, whilst a collection of pus presented itself in the pelvis, walled in by recent lymph and coils of intestine adhering to each other. The vermiform appendage was perforated by an ulcer, which communicated with the abscess, but no concretion could be found. The part where the gurgling had been heard on percussion was occupied by a loop of small intestine, situated over the cæcum and adherent by recent lymph to the adjoining parts.

Now, it is scarcely necessary for me to point out to many of you who have attentively listened to the narratives of these

Digitized by Google

two cases how remarkably they differ, although in each there was the same lesion of the vermiform appendage and the same local inflammation resulting from it. But in the former case general peritonitis had existed from the first, the symptoms were ushered in by sudden and intense pain, vomiting, and constipation; whilst in the latter the inflammation was confined to the part at which it had commenced; and the pain was never severe. The patient was, in fact, unable to fix the date of the beginning of his illness, and severe diarrhœa was the prominent symptom. But what we shall hereafter find was of great importance, was that in the first case the disease occurred in a person previously healthy and resulted from the irritation set up by a concretion; whilst in the second it took place in one who was suffering from long-standing phthisis.

From the fact of five cases of this kind having been admitted into this hospital within the last twelve months, you might infer that perforation of the appendix is by no means uncommon, but such is certainly not the case. During the last eight years only nine persons have come under my own care in whom the lesion was either proved to be present by post-mortem examination or in whom the symptoms were so well marked that the diagnosis could be made with tolerable certainty. Again, in carefully examining the post-mortem records of the London Hospital during the last forty years I have only been able to find nineteen in which the appendix was in a diseased condition. It is quite certain, however, that this number cannot truly represent all who have died in the hospital during so long a period of this disorder, for in the earlier volumes only one or two instances are recorded. But whether this may be the case or no, it is evident that the experience of no single practitioner will be sufficient to furnish him with instances of all the varieties the malady may present, and I have, therefore, collected 129 cases that have been published by different authors in the hope that from a careful study of so large a number we may be able to clear up some of the difficulties connected with the subject.

Of the whole number of cases collected only ninety-five have been recorded with sufficient details to enable us to ascertain the exact results of the perforation of the appendix, and of this number thirty-eight presented a localised collection of pus. Sixteen are said to have had an abscess in the neighbourhood of the appendix; and in all probability the condition was similar to what has been described in the two cases before quoted, where one or more coils of the small intestine were united to the surrounding parts and walled in the pus, or where it was situated in the pelvis and was surrounded by newly formed lymph. In twelve cases the pus was situated in the iliac fossa, in some around the cæcum, in others below the fascia, the muscular fibres being softened or broken up. A few instances are recorded in which the pus had burrowed upwards beneath the peritoneum, and had formed a huge abscess round the right kidney; in six instances the presence of an abscess is noticed, but its locality is not defined. But the question arises, Why in cases of perforation of the appendix is there this tendency to the inflammation of the peritoneum being localised, whilst in perforation of the stomach or small intestines such a condition so rarely occurs? No doubt the difference depends upon the nature and the amount of the material that is extravasated into the peritoneal cavity. In perforation of the stomach a large quantity of a highly irritating liquid is effused, which quickly finds its way to all parts of the abdominal cavity, exciting inflammation wherever it reaches; whilst in the case of the appendix the material is solid or in small amount, and being in the most depending part it does not at once reach the more distant portions of the peritoneum. We thus find that even where no abscess had been produced, it is mentioned that the inflammatory products were met with in the greatest quantity in the immediate vicinity of the cæcum, in the proportion of twenty-three cases out of ninety-five. It is easy to understand why only lymph should be found in one case and a collection of pus in another, for death probably occurred so rapidly in the former that there had not been time for the suppurative process to take place; but it is more difficult to explain why the abscess should be confined in one individual to the pelvis and in another to the iliac fossa. The most probable reason is that as the length and direction of the appendix vary in different subjects, so the seat of the inflammation must vary accordingly, being most intense at or [illegible] the nearest point to the perforation. When, for example, the [illegible] and has been the seat of the ulceration and it has [illegible] projected into the pelvis, the abscess will be situated in the hypogastrium or in the pelvis; but when the appendix has been very short, or placed behind the cæcum, or the perforation has taken place near its origin, the structures in or around the iliac fossa will be mainly implicated. Another circumstance that must tend to determine the position of the abscess is the formation of adhesions between the appendix and some of the neighbouring organs, which is recorded in ten cases out of the ninety-five. The cæcum, small intestines, the peritoneum, and the bladder were the organs to which the appendix was attached, and in some instances the adhesion had evidently occurred some time before the perforation had taken place. Various cases are on record where the appendix has been adherent to the inguinal canal, or has formed part of the contents of a hernial sac, and the pus has presented itself in the scrotum and been successfully evacuated.

It is evident that an abscess in the peritoneal cavity will usually set up so much constitutional irritation that death will ensue before it can be evacuated, but such is not always the case. In one instance at this hospital the pus was evacuated through the abdominal walls, and I have seen a very similar instance in my own practice. When it is situated near the cæcum it may burrow beneath Poupart's ligament, and may present itself in the thigh, as occurred in a boy who was under my care in the hospital two years ago, and who perfectly recovered after pus and fæces had been discharged from the wound. Other cases are recorded in which the pus has found its way into the cæcum, the ileum, or the rectum, and thus relieved the patient from imminent danger.

Of the whole number I have collected only one is mentioned in which pus was found in the abdominal veins, one in which abscess of the liver was present, five where pleurisy and two where pneumonia was discovered after death. It is doubtful whether we should not refer the pleurisy to the extension of the inflammation of the peritoneum through the diaphragm, but the others were most likely the results of the absorption of pus. When we remember how commonly pyæmia takes place in cases of deep abscesses of the limbs, we cannot but be surprised at the small number of cases recorded as following perforation of the appendix; but the explanation is not difficult. In the limbs large veins are numerous in the vicinity of an inflamed part; in peritoneal abscess the pus is walled in by adhesions, and the surfaces of the mesenteric veins are coated with lymph. In like manner we can see why abscess of the liver is so common a result of dysentery, and so unusual in peritoneal abscess; in the former the irritating and decomposing contents of the intestine are brought into immediate contact with the vessels laid bare by the sloughing of the mucous membrane; in the latter the pus is defended from immediate contact with the vascular system. But in those unusual situations of abscess resulting from perforation of the appendix, such as where the muscular tissue of the iliac fossa or of the loins is the seat of the suppuration, we will probably find that pyæmia is as apt to occur as when inflammatory action has arisen from other causes. Although the inflammation, as we have before seen, chiefly affects the lower part of the abdominal cavity, fifty-nine cases [illegible] out of ninety-five in which the whole peritoneal surface was implicated, and, judging from my own experience, I should be inclined to estimate the proportion still higher. Of course the amount of mischief varies greatly; in some cases the intestines are everywhere adherent, and collections of pus are met with in the most depending parts, [illegible] enclosed between the adjacent coils; in others lymph is uniformly spread over the surface of the membrane, and more rarely, we only meet with slighter [illegible] inflammation. General peritonitis occasionally [illegible] itself as the first indication of the perforation; in other [illegible] it travels slowly from the neighbourhood of [illegible] whilst more rarely it results from the bursting [illegible] abdominal cavity of an abscess set up around [illegible] and which had been circumscribed by adhesions [illegible] neighbouring structures. But at whatever [illegible] case the inflammation of the peritoneum may [illegible] almost always of a suppurative character, [illegible] which in all probability arises from the decomposition [illegible] of the substance which has originated the [illegible]

When this accident first attracted [illegible] it was remarked that the appendix [illegible] foreign body, and the idea arose that this [illegible] as regards this point; in fifty-five [illegible]

Digitized by Google

a concretion, a mass of fæces, or some other foreign body was present, and it is fair to conclude that the numbers would have been larger if a sufficiently careful search had been practised in them all; for as the contents of the appendix often drop into the pus surrounding the ulceration, it is easy to understand that a small concretion may frequently have been overlooked. The nature of the foreign body has varied, for in forty-seven cases sufficiently detailed to allow of analysis twenty-eight were concretions, fourteen consisted only of hardened fæces, and in five others, substances such as seeds or shell were present. But why should a foreign body in this part set up such serious results, when we know that in numerous instances the appendix has been found on post-mortem examination to be occupied by shots, seeds, and even, as in a case lately observed in this hospital, by lumbrici, without any apparent ill results; and when we so constantly meet with concretions in the kidney and the gall-bladder without any manifestations of disease having arisen from their presence? I think in most cases the presence of a concretion by its irritation gives rise to ulceration, and the proximity of the part to the cæcum filled with decomposing materials tends to produce sloughing in what would be otherwise a mere abrasion of the mucous surface. In support of this view I may mention that in sixteen cases the appendix is stated to have been in a gangrenous condition, although there is no notice in any of them of the cæcum being in a similar state. I think, too, we may find in the anatomical relations of the appendix a reason why in some instances perforation so readily occurs. In Case 1 you will remark that the ulceration had taken place in the centre of the process, where it was distended by the concretion, but the perforation was at the end. Now, the appendix is supplied with blood by means of a small mesentery of its own, which sometimes terminates before the extremity of the process, so that the end must derive its nutriment from the bloodvessels of the parts nearer to the cæcum, and under such conditions any acute inflammation or ulceration that obstructs the circulation must tend to rapid disorganisation of the structures. That this is by no means an uncommon cause of the perforation is shown by the fact that in the majority of cases the perforation is found at the extremity, and very rarely near to the cæcum.

Then how are the concretions produced? It has been generally assumed that they are the result of a secretion of the phosphates of lime and soda, of which they principally are composed, by the mucous membrane of the appendix, small nodules of fæces or some undigested particles of food which had obtained access to the part serving as nuclei. This is no doubt correct in many instances, as nuclei of this nature have been shown to exist in some concretions, but in others the calculus appears to be composed solely of earthy salts. Now, in one of the cases at this hospital it is noted that the appendix was distended by a milky fluid, the communication with the cæcum being obliterated, and in others recorded by different authors the appendix is stated to have been occupied by a substance resembling putty. It is, then, to obliterations of the valve, and consequent distension of the appendix with thickened secretions, that I suspect we must look not only for an explanation of the formation of many of the concretions, but also for the cause of some of the ulcerations that occur in which no foreign body can be discovered after death.

The second case I have narrated was one in which phthisis was present, and no concretion was discovered; and we might have conjectured that perforation would often occur under such circumstances, on account of the similarity of the structure of the mucous membrane of the appendix to that of the cæcum, which is liable to suffer from ulceration in this disorder. It is, however, much more rare for perforation to arise from tubercular ulceration than from the presence of a concretion, as I have only met with thirteen cases out of ninety-eight. Occasionally perforation occurs in typhoid fever, but I have only found six in which it took place in persons suffering from this disorder. Two cases have been recorded in which it happened during convalescence from other eruptive diseases; but there is no evidence that there was any connexion between the original malady and the abdominal complication.

It has been remarked by different writers that perforation of the appendix is much more liable to affect the male than the other sex, and this is borne out by the experience of this hospital, where of seventeen whose ages were recorded only three, or 18 per cent., were females, whilst of 105 cases collected from various authors only twenty-five, or 23 per cent., were of this sex. The proportion varies with the cause producing the perforation, for in the cases occurring in phthisical individuals 41 per cent. were females, and all of those that took place in the course of typhoid fever whose sex is mentioned were also females. When no foreign body was found in the appendix the proportion of females was 23 per cent., but amongst those in which a concretion or other foreign body was discovered after death there was only 17 per cent. It is evident from both sexes being equally liable in those affected with phthisis that there is no anatomical difference in structure which can account for the smaller proportion of females who suffer from perforation, so that we must seek for an explanation of the above facts in the habits or circumstances of the stronger sex. Now, it has been conjectured that the male is more liable to affections of the appendix on account of the more severe exertions to which he is exposed; and in support of this we may remark that in the first case the patient stated he had never been well since a strain received in his occupation, whilst other instances are recorded in which the fatal illness had been preceded by an injury to the abdomen. But, on the other hand, the history of an injury is only exceptional, and in the majority of cases the symptoms of the disease present themselves suddenly and without apparent cause. In addition to this, as we shall shortly see, the accident occurs more often in the young than in those at a later period of life, when severe labour is more generally undertaken. You will remember that I before suggested that many cases arose from obstruction of the valve, probably the result of catarrh; and this derives support from the fact that males are more liable to catarrhal affections of the cæcum than the opposite sex; for example, the numbers of cases of typhlitis admitted into this hospital for the last seven years have been fifty-nine, of whom only eighteen were females, which is at the rate of 30 per cent.

Let us now examine whether we can find any predisposing cause of ulceration of the appendix in the age of the persons affected. I have included all the cases whose ages are stated in the following table:—

Years of age.	Number of cases.
Under 10	9
10 to 20	29
20 to 30	21
30 to 40	16
Above 40	22
Total	97

It will be remarked that a considerable number have occurred under ten years of age, and half of these were under five; indeed, the accident sometimes takes place at the earliest period of life. From ten to twenty is the most usual time, and after thirty the numbers gradually decline. This is better seen if we divide the cases according to the cause producing the ulceration. Thus, if we examine only those in which either a concretion or some other foreign body was discovered, we find that thirty cases out of forty-three, or 70 per cent., occurred in those under twenty years of age, only four between twenty and thirty, and five between thirty and forty. If we separate those in which concretions were present from those where only particles of hardened fæces or other foreign bodies were discovered, the same liability is shown, as 64 per cent. of the latter and 80 per cent. of the former occurred under twenty years of age. But as we saw in the former table that a considerable number of cases of ulceration of the appendix occurred in persons above twenty, it is chiefly in those above this age in whom no foreign body has been discovered. In the next table I have included all the cases of typhlitis who have recovered and who were admitted into this hospital in the years before mentioned.

Years of age.	Number of cases.
5 to 10	2
10 to 20	24
20 to 30	25
30 to 40	2
40 to 50	5
Above 50	1
Total	59

It will be seen, on comparing these tables, that both ulceration of the appendix and inflammation of the cæcum are

Digitized by Google

most liable to occur between the ages of ten and thirty, when food is consumed in the largest quantity; and we may therefore assume that both affections depend upon a similar condition, and that the retention of indigestible materials in the cæcum and the catarrh so produced is the most usual cause. But as typhlitis and ulceration of the appendix are both common between the ages of twenty and thirty, although concretions are less common at that period than in the ten years before it, we are justified in supposing that a catarrhal condition of the cæcum, either by producing closure of the valve or by propagation of the inflammation to the appendix, often gives rise to ulceration, although no foreign body be present.

Most of the cases of ulcerated appendix in phthisical subjects occur at a later period of life than when it is due to the presence of concretions or catarrh, for out of those I have collected only one was below twenty years of age, seven were between twenty and forty, and three were above forty. All those connected with hernia were above forty years of age.

I have already mentioned the prevalent idea that the concretions so often found in the appendix are always the result of hardened fæces, or of indigestible materials of the food, and if such were the case we should expect to find that most of the sufferers had been liable to constipation. Now, I have collected forty-three cases in which the previous state of health is recorded, and of these only three had been subject to a constipated state of the bowels. It is therefore evident that this theory derives but little support from facts. I should be more inclined to believe that the concretions are in most instances the result of an excessive secretion of the mucous membrane of the appendix arising from the stimulus afforded by an undue use of solid and indigestible food. This view derives support from the fact that of twenty-five cases in which a concretion was discovered twenty are described as having enjoyed robust health, and three had been delicate; whereas of eight in whom no concretion was discovered, only five had been robust and three delicate. The presence of a concretion produces no pain until catarrh or ulceration is excited, for out of twenty-five cases of concretion only two had previously complained of abdominal pain; whilst of eighteen in whom no concretion was recorded five, or 30 per cent., had suffered in this way. I have before mentioned that injuries to the abdomen are supposed by some authors to give rise to ulceration of the appendix, and this derives some support from the fact that three cases out of eighteen in which no concretion was discovered referred their complaint to blows or strains. In four instances out of forty-three there was a history of a previous attack of typhlitis from which the patient had perfectly recovered; in two of these the patients died from peritonitis only, and in the remaining two both abscess and peritonitis were discovered after death.

(To be concluded.)

ON THE USE OF COCAINE FOR PRODUCING ANÆSTHESIA ON THE EYE.[1]

BY DR. CARL KOLLER.

TRANSLATED AND REVISED BY J. N. BLOOM, B.A., M.D.

GENTLEMEN,—I take the liberty of addressing you in order to inform you about some experiments which I have undertaken in order to produce anæsthesia on the eye. It is not the first communication which I have made on this subject. I have already addressed such a one, in order to preserve my priority in this discovery, to the Convention of German Oculists, which, as it annually does, met on the 15th and 16th of September in Heidelberg. Dr. Brettauer of Trieste was kind enough to bring my communication into notice and to repeat my experiments before the Convention, and since then the same have been repeated and confirmed in various other places. ... ...

It is a well known fact that cocaine, an alkaloid produced in 1859 by Nieman from the leaves of the erythroxylon coca, possesses the peculiar property, by its local application, of anæsthetising the mucous membrane of the tongue. Prof. Schroff mentioned this fact for the first time in 1862 in a lecture on its nervous effect read before this assembly. It is also well known that cocaine narrows the peripheral arteries when taken internally; further, we know that cocaine dilates the pupil by means of its local application as well as by its internal use. We therefore see that cocaine has already been applied to the eye, but until now those phenomena have not been observed which I make the object of my discourse to-day. After repeated experiments with its internal use cocaine fell into discredit and disappeared from the scene. Dr. von Anrep in 1880 produced a comprehensive research into cocaine, at the end of which it was hinted that the local anæsthetising action of cocaine might in the future become of considerable importance. In Vienna, especially, cocaine has been brought to the front through the interesting therapeutical work of my colleague in the general hospital, Dr. Sigmund Freud.

I have started with the premise that a substance which paralyses the terminal sensory nerves of the mucous membrane of the tongue would not act very differently on those of the cornea and conjunctiva; so I undertook a series of experiments on animals, which I carried out in the laboratory of Prof. Stricker. My results, in brief, are as follows:—If a few drops of an aqueous solution of muriate of cocaine[2] are dropped upon the cornea of a guinea-pig, a rabbit or a dog, or if the solution is instilled in the usual way into the conjunctival sac, the animal blinks for a while, clearly as the result of a weak irritation. After a period of from thirty seconds to one minute the animal opens its eye, which gradually assumes a peculiar expression of rigidity. If one now touches the cornea of the animal with the head of a pin, being careful not to come in contact with the eyelashes, no reflex closure of the lids occurs, the bulb does not deviate, and the head is not thrown back, as would otherwise happen. On the contrary, the animal remains quiet, and by the employment of a stronger irritation we can convince ourselves that the cornea and conjunctiva are completely anæsthetised. For instance, I have scratched the cornea of the animals upon which I experimented with a needle, pricked the same, irritated the cornea with an induction current which was so strong that it produced a painful sensation in the fingers and was unbearable on the tongue, and cauterised their cornea with a pencil of nitrate of silver until it became as white as milk; all without a single movement on the part of the animals. The last two experiments convinced me that the anæsthesia included the whole substance of the cornea, and not only its surface. However, after I had cut into the cornea, the animals showed decided signs of pain at the moment, when the aqueous humour gushed out and the iris prolapsed. Even in my later experiments on animals I was unable to determine whether the iris also could not be anæsthetised by the instillation of the solution into the corneal wound, or by a continued instillation into the conjunctival sac, begun and kept up for some time before the operation; for experiments testing sensibility of animals which are not narcotised are very difficult, and, especially if they are in the slightest degree complicated, are apt to give equivocal results. I had yet to find out experimentally whether cocaine could produce anæsthesia of the inflamed cornea, and this question was answered in the affirmative, when the animals upon which I produced an artificial keratitis, by means of a foreign body, showed the same anæsthesia of the cornea as the healthy ones. Complete anæsthesia lasts on the average ten minutes, when a 2 per cent. solution is used.

After such successful experiments I did not hesitate to apply cocaine to the human eye. At first I experimented upon myself and a few colleagues; later, on a large number of other individuals; the results of which without exception proved that the cornea and the conjunctiva were thoroughly anæsthetised by its use. The sequence of the symptoms is as follows:—When a few drops of a 2 per cent. solution are introduced into the conjunctival sac, or, better still, if they are allowed to run over the cornea, together with an increased secretion of tears, a slight burning sensation is felt, which disappears after an interval of from thirty seconds to a minute, to give way to an obscure feeling of dryness. To the observer an eye thus treated has a peculiar rigid expres-

[1] A paper read at the meeting of the Vienna Royal Imperial Society of Physicians on Oct. 17th, 1884.

[2] A solution of cocaine in water, up to 5 per cent., can be made without the addition of an acid. The solution is always cloudy. The addition of an acid [illegible] as even a very small quantity of an acid causes a very [illegible] solution. When filtered the solution becomes [illegible]

Digitized by Google

sion, very like that which I noticed as remarkable on the animals upon which I experimented. This expression arises from a decided widening of the palpebral fissure, the explanation of which I shall give later. If now the head of a pin is brought in contact with the cornea we note the absence not only of the pain usually associated, but we absolutely do not feel the contact, and all reflexes are absent. The same holds good for the conjunctiva, which loses its sensibility to heat and cold. Without any inconvenient sensation, or the slightest reflex movement on the part of the patient thus treated, we can grasp the conjunctiva of the bulb with a toothed forceps, or we can pit the cornea by pressure. In this connexion the only thing to be observed is that the appearance of objects becomes indistinct, which naturally is caused by the changed curvature of the cornea. This complete anæsthesia lasts from seven to ten minutes, to give way to the normal condition after a considerable period of subnormal sensibility. From fifteen to twenty minutes after the instillation the pupil begins to dilate; the dilatation reaches its maximum during the first hour, decreases decidedly in the second hour, and disappears completely in a few hours more. The dilatation is never a maximal one, and during the whole time the pupil reacts promptly to light and on convergence; therefore the feeling of dazzlement which is connected with atropia-mydriasis is either entirely wanting or is present to a slight degree only. With mydriasis there appears and disappears a very slight paresis of accommodation; the near point of myself and one other person whom I examined for this purpose was lengthened half an inch. I have observed in the normal conjunctiva, especially in the conjunctiva palpebrarum, a decided ischæmia, about the duration of which I can say nothing certain. I shall for the present pass over certain other observations not yet completely confirmed, as, for instance, those concerning the appearances shown by the ophthalmoscope, only stating that I have never seen any symptoms of irritation arise from the use of cocaine. As for the previously mentioned widening of the palpebral fissure, the symptom precedes in point of time, at any rate, its action on the iris and ciliary muscles, and as it appears almost simultaneously with the anæsthesia of the cornea and conjunctiva, I have referred it to the anæsthesia as a cause, and explained it by the disappearance of the irritations which normally affect the cornea and conjunctiva and cause the usual width of the palpebral fissure. As regards the anæsthesia, I have still some practical and important points to bring forward.

1. The anæsthetic effect of cocaine can be increased to a certain limit—that is, if cocaine is dropped into the eye after the partial cessation of the anæsthesia, a second complete anæsthesia results which lasts longer than the first. In this way I have produced complete anæsthesia lasting from fifteen to twenty minutes from the last application by a continuous repetition of the application at intervals of five minutes. 2. The anæsthetic effect is pre-eminently a local one—i.e., it is stronger on those places to which the solution has been directly applied and where it has been for some time in contact. 3. Since, as may be proved, cocaine is absorbed, and after every instillation a quantity, even though small, reaches the anterior chamber, one would *a priori* expect that the deeper portions of the eye could be rendered anæsthetic were it possible to introduce larger quantities of cocaine into it. But as, on the one hand, a certain time is necessary for its absorption, and on the other the anæsthetic effect in point of time is limited, the anæsthesia of the cornea would be over when the iris and ciliary body began to be affected; it would therefore be necessary to anæsthetise the cornea again. I believe I can meet both of these conditions, as the following will show. By means of a continuous application repeated every five minutes with a 5 per cent. solution kept up for some time (about half an hour) I succeeded in producing such an effect upon the deeper parts of the bulb that its sensibility to strong pressu was very decidedly diminished.

Through the kindness of Professor von Reuss, who placed at my disposal for experimental purposes the material of his (formerly Jaeger's) clinic, I was able for two or three weeks to test the effect of cocaine upon the pathological eye. From the very beginning I held cocaine to be valuable therapeutically for two purposes; one for its use as a narcotic in painful diseases of the eye; the other as an anæsthetic in operations on the eye. As for its use in the first instance, I expected much good from its action, especially in diseases of the cornea and conjunctiva, where there is much pain and intolerance of light. Indeed, I used cocaine in a 2 per cent. solution on a large number of patients with conjunctivitis pustulosa (herpes corneæ). Several minutes after the instillation all the patients thus treated expressed an improvement as regards their subjective condition. The pain was diminished and the intolerance of light was decidedly lessened. With the same unanimity the patients complained that the pain and intolerance of light returned two or three hours after the instillation. We would expect that the pain and intolerance of light could be done away with, or at least diminished, by a frequent application. This method of application could not be carried out up to the present time because of the expense of the drug. I have not observed any influence, beneficial or otherwise, on the course of the disease in the experiments I have made as given above.

Similar results were obtained by me with the use of cocaine in the case of a man with painful erosions on the limbus. I hope also to control the pain in iritis by the use of cocaine, since I believe I have previously shown that its anæsthetic action includes to a certain extent the iris and the ciliary body. The mydriatic effect would not be of so much importance; still one might expect an influence upon the course of the disease from the vaso-constricting power of the drug; perhaps combined with atropine it might be successful. Up to the present time I have had no opportunity of using it in this disease.

The pain connected with cauterisation of the conjunctiva with nitrate of silver is entirely done away with, or, at least, decidedly lessened, by the previous instillation of cocaine. Most of the patients thus treated experimentally expressed themselves as having experienced no pain. In some cases, after a period of latency, the pain appeared, but after a fresh instillation it disappeared. One patient asserted that the pain, although much less than usual, lasted longer. I have little, and, in part, contradictory experience in the use of cocaine with the sulphate of copper treatment; at any rate, in this latter use it must be applied much stronger than in cauterisation with nitrate of silver.

I come now to the second use of cocaine—namely, as an anæsthetic in operations on the eye. Cocaine is used with excellent results in the removal of foreign bodies from the surface and substance of the cornea, an operation which is often rendered so difficult by the restlessness of the patient. I anæsthetised a considerable number, almost thirty, of such patients, making each, either seated or standing, look downwards, and allowing two drops of a 2 per cent. solution to flow down the cornea. After a period varying from three to five minutes the instillation was repeated. All the patients thereupon asserted that they had lost the sensation of a foreign body in the eye, and believing it was removed, prepared to go home. They held their bulb quiet during the extraction of the splinter by means of needles, and when asked what they had felt answered that they had felt nothing at all. Cocaine was used with the same good results in a case of tattooing of cicatrices on the cornea, and in the operation of pterygium. Good results might be obtained with cocaine in cauterisation of corneal ulcers with the actual cautery in the puncture of the cornea and discissio cataractæ.

Dr. Reuss performed the operation for staphyloma upon two children—one a boy, aged ten years, the other a girl of seven—without narcosis, using only cocaine in the manner to be described later on. The children remained perfectly quiet, and, according to their own confession, experienced no pain. Dr. von Reuss kindly allowed me to employ cocaine in several cases of iridectomy and cataract operations after Graefe, which he performed. In general, I only wish to state that these cases, one and all, ran their course without any irritation, and this, to say the least, calls for further trials of the drug. The experimental use of cocaine gave results which were more or less favourable according to the strength of the solution and the manner in which it was employed. The most favourable and almost completely satisfactory results as regards painlessness in operations were given by the cases in which the following method was carefully observed. For at least half an hour before the operation two drops of a 5 per cent. solution are instilled every five minutes. The patient is placed horizontally (without a pillow under the head), the upper lid is elevated, and, while the patient is told to look towards his feet, the solution is dropped upon the sclera just above the cornea.

Among those so treated was a woman, upon whom a linear extraction was made and who was questioned during each

Digitized by Google

stage of the operation; she answered that she felt absolutely no pain from the corneo-scleral incision, the seizure and cutting off of the iris caused her but little pain. During the whole operation there were no reflex movements. A like result was obtained in the case of an idiotic woman upon whom the same operation was performed, and upon whom Dr. von Reuss hesitated to operate because she was in other respects very sensitive.

The following case appears to me to be worthy of notice on account of its peculiar circumstances. Iridectomy was performed upon the left eye of a man with a bilateral seclusio pupillæ. Cocaine was employed. The man did not move in the slightest degree during the operation, and asserted he did not feel the corneo-scleral incision at all; that he felt the seizure and cutting off of the iris, but it did not pain him. Eight days later the other eye was operated upon, but this time without the use of cocaine; he writhed and "bore down," so that the operation was rendered decidedly more difficult. Although a large majority of people who have to undergo such operations are torpid individuals and bear their pain with patience, nevertheless, the last case appears to me to prove that even in such cases an anæsthetic might be of excellent service.

The translator of the above paper on the anæsthetic use of cocaine has been requested by the author to add the following short notice, the results of later experience in the use of the drug. Lack of time and space prevent details. Operations for cataract are almost painless when performed with cocaine. Hence in those cases of prominence of the bulbs, where there is great danger of escape of the vitreous humour during the operation, the elevator has been dispensed with. The importance of this will be appreciated by oculists. As predicted by Dr. Koller when he wrote his article, the operations of puncture of the cornea, discissio cataractæ and cauterisation of corneal ulcers have since been frequently performed under the cocaine anæsthesia, and absolutely painlessly.

That cocaine is of great value in relieving pain in iritis, the following case, given in brief, will show:—

A woman, M. F——, forty-five years old, in Dr. von Reus's wards, suffered so much pain from iritis as to be unable to sleep. The insomnia was complete, and had lasted seven days and nights. Atropine had been employed continuously. Cocaine in 5 per cent. solution was instilled six times in half an hour in the manner already detailed. The pain disappeared completely but reappeared three hours later. Cocaine was again instilled; this time three times in fifteen minutes. The pain vanished and the patient slept comfortably for the rest of the night. The next day on the reappearance of the pain a third instillation was used, and the pain disappeared and did not return.

In the clinic of Dr. von Reuss nearly all the operations are now performed under the cocaine anæsthesia according to the method already given in detail.

NOTE ON THE VALUE OF HYDROCHLORATE OF COCAINE IN OPHTHALMIC SURGERY.

BY J. CRAWFORD RENTON, M.D. EDIN.,
SURGEON TO THE EYE INFIRMARY, GLASGOW.

FOLLOWING the recommendation of Dr. Koller of Vienna, which was brought under my notice by Mr. Marcus Gunn of London, I have recently been using the hydrochlorate of cocaine in all operations on the cornea. Two per cent. and four per cent. solutions, some made with distilled water alone, others with boracic acid and glycerine to prevent putrefaction, have been used, as also the discs of the strength of $\frac{1}{300}$ gr., made by Savory and Moore on the suggestion of Mr. Nettleship, and I have no hesitation in saying that my best corneal anæsthetic results have been obtained with the discs, two being quite sufficient to produce complete anæsthesia in six minutes, and being maintained from fifteen to twenty minutes. The 2 per cent. solution in distilled water acted well, but that made with glycerine was not satisfactory. One patient, who had both solutions used in a double iridectomy he required for lamellar cataract, stated that he felt no pain whatever with the plain solution, but slight pain with the glycerine preparation. In cataract extractions and needle operations the anæsthesia of the cornea is most satisfactory, and patients state that they feel no pain. For the removal of foreign bodies from the cornea the cocaine promises to be most serviceable. As a mydriatic, in some patients it is very decidedly so, our present house-surgeon, Dr. McIntosh, who kindly allowed me to use it in his eye, found that his pupil remained fully dilated for a week. As a controller of ciliary pain I have not yet found the cocaine of much value, nor have I been able to satisfy myself that the conjunctiva or skin is much affected by it; but its value in preventing pain during an operation and keeping the eye soothed for some time after cannot fail to conduce to good results in ophthalmic surgery.

Glasgow.

CHOLERA.

BY MAX VON PETTENKOFER, M.D.,
OF MUNICH.

(*Continued from page 905.*)

THE same considerations hold good in India. The famous places of pilgrimage, whose sanctuaries are annually visited by many millions of individuals, always have some cases of cholera amongst them, but it is only occasionally that an epidemic breaks out, and then it is only at those times when the predisposition to cholera exists—periods, be it noted, which do not for the most part coincide with the time when the number of pilgrims is at its greatest, nor when the principal feasts are in progress. For instance, Bryden has drawn up tables showing the number of admissions into the hospital at Puri in the neighbourhood of the sanctuary called Dschagganath for the years 1842 to 1866, and these statistics show the number of receptions of cases of cholera for each month of the year. This journal, extending over so many years, must give a good idea of the frequency of cholera in pilgrimage even though the numbers be but small. The principal feasts, when the chariot of the deity is drawn over the breasts of the faithful, occur in the middle of March, but the period at which cholera is at its height is in June, when there are many fewer pilgrims assembled. Altogether there were 313 cases in March during twenty-five years, whilst the number was 1155 for June, or nearly four times as many admissions for cholera into the hospitals. Puri lies on the south-west border of the territory where cholera is endemic, and has the same rhythm so far as cholera is concerned as Madras. Hardwar lies in the north-west of India, where the chief feast occurs in April, the principal day being the 12th, and often hundreds of thousands of pilgrims, if not millions, stream together here; yet cholera only breaks out in an epidemic form when the regions are predisposed to it. It will be interesting to go further into detail on this question. Hardwar is situate about 1000 feet above the level of the sea where the Ganges quits the Himalayas, and belongs to the holiest of places which the Hindoos worship. Cholera only occurs occasionally in an epidemic form. In the last century (1783) a severe epidemic was known to have occurred amongst the pilgrims at Hardwar. From 1858 to 1867 the feasts passed on without the occurrence of any epidemic of cholera, and this immunity was believed to be due to the soundness of the arrangements which were enforced by the Government. In 1867 the whole prophylactic armour was thrown aside. But already in November, 1866, an epidemic of cholera was approaching the neighbourhood of Hardwar from Agra. The pilgrims began to arrive at Hardwar on April 1st. On April 3rd the majority had assembled, although the stream of pilgrims continued to increase till the 12th. The whole number of pilgrims reached about three millions. On April 9th the first case of cholera was detected by Dr. Kindall and taken into hospital. Other cases soon followed. On April 12th, on holy day, the pilgrims bathed from sunrise to sunset in the Ganges, in a holy fort which is separated from the torrent of the river by a rail, so that the people could not be drowned. Through this fort there was an incessant movement of men all day long. The water became thick and muddy, partly from the ashes of the dead which the pilgrims had brought with them to strew in the stream, and partly from the washing of the clothes and persons of the bathers. Every time a pilgrim entered the holy fort he dipped himself three times under, drinking the

Digitized by Google

water and saying his prayers. The drinking of the water was never forgotten; if two or more members of a family bathed together each one drank from the palm of another's hand. All these things happened every year for eight years without ill consequences. But in 1867 a violent epidemic broke out among the pilgrims. Macnamara, a believer in contagium and in the drinking water theory, speaks as follows: "On the night of April 11th and on the following day a severe storm burst upon the unsheltered multitude. Only those who know what a storm on the mountains in the tropics is can have any conception what a night of misery these three millions of people suffered on the open plains of Hardwar. This fall of rain must have washed the contents of the closets and the filth on the surface of the earth into the Ganges." And Macnamara believes that on April 12th the pilgrims drank cholera from the Ganges; but Macnamara is wrong. Granted that the storm had really washed the cholera stools into the Ganges, then the stools must have remained either in the river itself or else in the holy fort, just as was the case in Koch's water tank. It is true I can find no numerical observations concerning the rapidity of the flow of the Ganges in Hardwar; but if we suppose that its rate is like that of the Seine in Paris at low water—i.e., half a foot per second,—then the water would move at the rate of 1800 feet an hour. The railed off fort in which the pilgrims bathed is 650 feet long by thirty feet wide, and if the bathing lasted twelve hours, and if only a third part of the pilgrims had bathed, then more than 83,000 persons must have hourly passed through the water; this was impossible, so that only a small proportion of the pilgrims could have bathed on April 12th. These places of pilgrimage are also colossal markets and great places of business. It does not support the drinking-water theory to assume that during the bathing of the 12th that cholera bacilli did not get into the holy fort from cases of cholera which would hardly be in a condition to bathe, but from cases of diarrhœa. Either a few of the bathers were, to start with, infected, and so large numbers could not be infected until the bacilli had become distributed, or if a large number were infected at the outset, we naturally inquire where the infection was taken, and whether there was no possibility of their having been infected before going to the bath. If I do not believe that the pilgrims drank death from the holy stream, yet I shall not maintain that the stormy weather had nothing to do with the cause of the epidemic. Cases of this kind have occurred outside India, as in Malta and Spezia in Italy, where a sudden storm has sent up the death-rate in an explosive fashion. But if a weather storm can create a "cholera storm," then the cholera must be existent in the soil. One is reminded by this invasion of cholera of the clouds of dust which the watering-carts raise in summer. If the earth is very dry, the water not only lays but makes dust. I can conceive how a sudden heavy fall of rain may rapidly drive out the infective stuff contained in the soil. But Hardwar had experienced bad weather in other years on the same days in April without being followed by such evil consequences.

How does the journey of the pilgrim act in the spread of cholera? That infection can occur in a short space of time is witnessed in soldiers on the march. A case from Bryden's work may be quoted. In March, 1857, the 66th Ghorka Regiment marched simultaneously in two divisions about seventy English miles apart, from the plains to the hill stations along the Himalayan heights—the A division towards Almorah, the B towards Lohnghat—and both wings, though free from cholera on starting, became infected *en route*. The A division, 611 men strong, arrived on the 13th of March free from cholera at Tarai, a narrow strip of land between the plain of the Ganges and the Naini valley. Tarai is notorious for its fevers and cholera, whilst the Naini valley is celebrated for its general salubrity and its remarkable freedom from epidemics of cholera. The division left Tarai the morning after its arrival, passed into the healthful Naini valley, and halted at the hill station of Almorah. The first case of cholera showed itself in the Naini valley twenty-four hours after the first opportunity for infection. The first fatal case occurred on March 16th, two deaths occurred on the 17th, ten on the 18th, nine on the 19th, and one on the 22nd. These numbers show a mortality of nearly 10 per cent. The B division was 361 strong, and passed through Tarai about a week after the A division, remained there but one day, and reached Lohnghat on the 23rd of March. The first fatal case occurred on March 21st, whilst the division was still in Tarai; there were 2 fatal cases on the 22nd, 18 on the 24th, 8 on the 25th, 1 on the 26th, and 1 on the 27th. Fatal cases thus occurred within a period of seven days. Such statistical facts, which might be multiplied, have as much value, as direct experiments, as infection through the linen of cases of cholera. It is strange, however, that most of the "cholera linen" first originated in the Naini valley, in Almorah and Lohnghat, where the disease did not spread further and where certainly disinfection by carbolic acid or corrosive sublimate was not thought of. But the contagionists have no eyes for such facts. Just as was the case with the Ghorka Regiments, so was it with the pilgrims at Hardwar. On April 15th the great mass of the pilgrims—who had been quartered on a flat, partly marshy, tract of land, about a square mile in extent, for several days—broke up and departed, so that a stream of 3,000,000 of infected individuals for the most part, notwithstanding the influence of the bathing in the Ganges, reeking with filth, began to spread abroad over all India. According to the contagionists, an epidemic of cholera ought to have broken out in every place to which the wandering pilgrims came. In my view epidemics may break out only where the time and local conditions are favourable; and where these conditions do not exist an epidemic is impossible, as the case of the Ghorka Regiments proved. Bryden expresses himself in the following terms on the Hardwar cholera. "From all accounts which have been written concerning the outbreak at Hardwar, the impression is gathered that the epidemic was by no means a typical one. That is only the case, however, if the facts are considered in the light of preconceived theory. For those who search the statistics the facts come out in their true light, and prove that the type of an epidemic has nothing to do with the smallness or largeness of the number of people affected. The suppression of the cholera at Hardwar towards the east and south, and the increase of it in the west and south-west, are inexplicable phenomena [Bryden ought to have said, for the contagionists]. But the phenomena are not difficult to understand if the preconceived theory be laid aside. If we take Hardwar as the central point at which the gathering on April 12th was infected, then it will be found that the pilgrims died only in those districts which were reached within a limited time after their daily march had begun. The great majority of fatal cases did not occur at Hardwar, but in those regions which were reached within the first few days after leaving Hardwar. It seems to me that the end of the outbreak at Hardwar was pretty much the same as that of local outbreaks elsewhere, and I can see no connexion between the epidemic of cholera in the Punjaub in May and the return home of the pilgrims." The movement the cholera had taken in the autumn of 1866 led Bryden to say, "I believe that the geographical distribution of cholera in 1867 would not have been very different, even supposing that the gathering of the pilgrims had never taken place." And Bryden is perfectly right, for in 1862, for example, the cholera in India became remarkably widely spread without cholera having broken out amongst the pilgrims at Hardwar.

Such epidemiological facts which cry aloud for the truth of the existence of local and time predisposition stand as sure, as etiological elements, as the discovery of a microscopic organism in the intestines of cholera patients. Only ignorance and prejudice can ignore such facts. It is but a necessary logical conclusion that the comma bacillus, if it have anything to do with the infective material of cholera, must also have some relationship with the local and time conditions which favour cholera. And, further, the relationship must be discovered by the bacteriologists before they can explain as epidemic by the aid of their bacilli and before practical rules can be framed thereon.

Another objection to the views of the contagionists is found in the behaviour of cholera on board ships. Long before I announced my views on local conditions, the epidemics of cholera, not only on the rocks of Malta and Gibraltar, but also on ships, were brought as witnesses against my doctrines. What can soil and ground water have to do with epidemics on ships? And although I had found nothing but confirmatory evidence of my views, still the contagionists remained obdurate. As I cannot suppose that all my readers are sufficiently acquainted with my observations on cholera in ships, I must be allowed to give a few illustrations. The contagionists, referring to cases in which epidemics occur during the voyage from Europe and

Digitized by Google

America, say that such can only be explained on the view of infection of one case from another. The facts of such epidemic outbreaks are known to all. How often do such attacks occur? As an instance, I shall refer to the intercommunication between New York and Europe in the year of cholera 1873. In that year, according to the register of the offices at New York, there were 760 vessels which arrived from different parts of the world, giving an aggregate of 316,956 individuals, but of these 266,055 came from Europe. Of these 113,920 came from England, which was free from cholera; from the remainder of Europe the numbers were 152,135, and about 400 vessels served to convey the individuals, making up the last figures, from ports infected with cholera. If we inquire into the statistics we find that cholera chiefly occurred on four vessels only. Eleven cases were registered from the *Westphalia;* one fatal case from the *Ville du Hâvre;* from the *Washington* three fatal cases; and from the *Holland* one fatal case.

Although the chances of contagion aboard ship are very favourable, yet how small was the number of cases of cholera. Take the ship with eleven cases, and we find that they belonged to two German families only; two died during the voyage, nine were landed on Dix Island, and of these but one died and the rest recovered. How is it conceivable that cholera should have confined itself to two families without attacking others? I believe that both families had contracted cholera before going on board; indeed, an epidemic may occur in a ship provided the passengers have all come from a place where cholera exists. The contagionists have, however, replied that some remarkable epidemics have happened on board ship, which could not be explained on the above mentioned view. It is a question whether cholera can infect on board ship. The contagionists take facts conveniently, they select those instances which occur least frequently and adopt them, to the exclusion of the great majority of instances which tells against them. I recall the articles which I wrote in the *Vierteljahresschrift für öffentliche Gesundheitspflege* and in the *Zeitschrift für Biologie* to prove that I have thoroughly investigated the nature of epidemics of cholera on ships. Rumours of false returns concerning cholera on board ship have been bruited. But these falsifications can hardly be committed when *an epidemic* occurs during a voyage. It may be said that my instance of 1873 does not disprove the contagiousness of cholera. Cholera, like small-pox, does not attack everyone who is brought into relationship with it. If even a few instances of contagion were proved to have occurred on board ship, we should have to admit the contagiousness of the disease.

(To be continued.)

TWO CASES OF CHARBON.[1]

BY A. F. M'GILL, F.R.C.S.,
SURGEON TO THE LEEDS GENERAL INFIRMARY.

THE two cases which form the subject of this paper are examples of a disease which manifests itself in many various ways, and which has received several names, but which is distinguished by the presence of a characteristic organism, the bacillus anthracis. The cases apparently have but little in common. In the first the symptoms were mainly general; in the second local. The first proved rapidly fatal, the second terminating in recovery.

CASE 1.—A butcher, aged sixty-four, at the time in perfect health, was on July 23rd skinning a beast which had that day been slaughtered. The beast was known to be diseased, several other animals in the same pasture having previously been affected; its spleen was found to be greatly enlarged and soft. The man while examining the viscera to find out the nature of the ailment, knocked a small piece of skin off the lower part of his right forearm. The next day his hand was swollen, and he felt ill; on the evening of July 25th, two days after the accident, he applied to and was admitted into the Leeds Infirmary. On admission the forearm was seen to be enlarged, tense, and shining, the swelling extending above the elbow; there was a small excoriation above the wrist, which did not present any unusual appearance; the lymphatic glands in the axilla were not enlarged. He seemed depressed and ill, but not more so than the local disturbance would account for; his temperature was 100°. There were no unusual symptoms about the case, which was looked upon as ordinary diffuse cellulitis. Numerous incisions were made in the forearm and arm, and a poultice was applied. The next day (July 26th) the condition of the arm remained stationary, but the general condition was worse. The temperature was only 100°, both morning and evening, but the appearance was pinched and the aspect bad. On July 27th the temperature had fallen to 97·4°; the following note was made at noon:—The body and extremities were cold; the pulse could hardly be distinguished; the aspect was pinched and death-like. Yet his mind was clear, he could give a lucid account of his accident, and was not aware of his dangerous moribund condition. At 4 P.M. Dr. Barrs examined the serum and blood obtained from his arm. These fluids did not contain any organisms. At 6 P.M., four days after his inoculation, the patient died. A post-mortem examination was made twenty-two hours after death. The following notes were taken from the post-mortem register:—Rigor mortis present; body well nourished; right arm and forearm along the inner side were swollen and red, with many small punctures visible. There was a small unhealthy-looking abrasion at the point of inoculation on the right forearm. The tissues on the front of the chest were œdematous, and the pectoral muscles soft. The lungs were soft, congested, and œdematous; spleen very soft and diffluent; kidneys normal; liver slightly fatty; other organs healthy. Dr. Barrs examined several specimens of blood obtained from various parts of the body, and found that quantities of the bacillus anthracis containing spores were present. Mr. W. B. Russell examined the spleen pulp, and also found large numbers of the same organisms.

CASE 2.—On August 6th I saw a middle-aged man who had been under the care of Dr. Nowell. Four days before, while dressing a beast, which had been feeding in the same fields as that mentioned in the last case, and which also had an enlarged spleen, he scratched his right arm about an inch above the wrist. He thought nothing of it at the time, but in two days his forearm was swollen and a circumscribed sore appeared at the seat of the scratch. This sore gradually but rapidly increased in size. When I saw it, it presented the typical appearance of a malignant pustule. There was a black dry patch, rather larger than a shilling, situated an inch above the right wrist on the centre of the flexor aspect of the forearm, this was surrounded by a reddish-purple zone covered by small indistinct vesicles, and gradually faded into the surrounding skin; the whole forearm was considerably swollen. There was not much constitutional disturbance, though the patient was somewhat feverish, flushed, and anxious. I recommended immediate excision, and after consultation with Dr. Newell excised the pustule the same afternoon, cutting wide of the inflamed skin in all directions. The wound was dressed with iodoform, freely applied, and silk. On September 18th Dr. Newell kindly sent me a note of the further progress of the case. He says—"The case of malignant pustule has progressed well; iodoform and dry lint were used as dressings until about a fortnight since, when I substituted resin ointment, once or twice touching the weaker prominent granulations with silver nitrate. He came for the last time on the 15th, but promised to call and let me see the wrist by-and-bye. The wound is now healed and evenly filled up except an oval about the area of two lines by one." The pustule at the time of removal was placed in weak alcohol and subsequently examined by Dr. Jacob, who has furnished me with the following report:—"The pustule when hardened in alcohol still preserved its black centre, with a trace of the red areola. A section through the centre showed considerable necrosis of the epithelioid elements with partial separation of the epidermal layer by sero-fibrinous and cellular infiltration. A section stained with gentian violet and resin showed a large number of bacilli and spores scattered over the field, occupying the deeper as well as the more superficial layers of the corium. The bacilli were thick, short-jointed rods, the spores large and rounded, resembling rather those obtained by cultivation of the bacillus anthracis in meat infusion than those generally found in cases of anthrax in man. There were besides several collections of micrococci of the ordinary septic type."

There are several points which require notice in relation to these cases.

1. In the first case, though a careful examination was

[1] Read before the Leeds and West Riding Medico-Chirurgical Society.

Digitized by Google

made, no specimens of the bacillus could be discovered in the patient's blood two hours before death, though at the post-mortem examination large numbers were found. This is often the case—indeed, it seems that life cannot be carried on when the bacilli in considerable number are present in the blood. The bacilli cannot live without the presence of oxygen, and as soon as they are developed in the blood, they speedily deoxygenate that fluid, rendering life impossible. It is probable that the spores of the bacillus circulate in the blood during the continuance of the disease, and it has been proved by experiment that they thrive without oxygen; as soon as the time comes for them to be developed into bacilli the patient dies.

2. The condition of Case 1 on the day of his death forcibly reminded me of a patient dying from cholera collapse. There was the same cold and clammy body and extremities, the same pulselessness, the same rapid breathing, and the same remarkable clearness of the mental faculties.

3. The satisfactory result which attends the early excision of malignant pustule is again exemplified. The success of this treatment has been proved at Guy's Hospital, where of fifteen cases in which excision was practised, thirteen made a good recovery. At Guy's it has been customary to apply chloride of zinc or some other strong caustic to the wound caused by the excision. Microscopic examination, however, proves that the bacillus is not found in the subcutaneous tissue, and this case shows that the application of a caustic is unnecessary.

4. As animals which die of splenic fever are in this district disposed of in the usual manner and sold for human food, it is interesting to know what is the effect of the bacillus when taken into the stomach. Koch made some experiments on sheep, with the object of elucidating the point. He found that sheep might be fed with unlimited quantities of the bacilli free from spores, and that no bad result occurred; but if the virus contained spores in an active state of development, death invariably occurred within two days. Fortunately the meat that is eaten will all be cooked, and we may hope that the bacillus is thus destroyed, and that no harm results. But the risk that is run by the persons who have to prepare and dress the meat derived from diseased carcases is only too evident. While meat of this description is sold in the open market, we should remember that cases of charbon may come under our notice, in which it will perhaps be impossible to ascertain the mode of infection.

SOME OBSERVATIONS ON THE

SPINAL CORD IN HEALTH AND DISEASE AT THE REGION OF THE FOURTH AND FIFTH DORSAL VERTEBRÆ.

BY ALEXANDER HARKIN, M.D., F.R.C.S.,

CONSULTING PHYSICIAN TO THE MATER INFIRMORUM HOSPITAL, BELFAST.

(*Concluded from p. 58.*)

CASE 1. *Paralytic chorea.* — This case, the first of which I have any record, occurred in 1850. It was that of a bank clerk aged eighteen years, of bilious habit and sluggish intellect. He was ill with paralytic chorea and what is now termed symptoms of incoördination and defective inhibition. His left hand had become unmanageable; he could not retain the hold of a pen, a teacup, or a book for a moment; and the loss of control extended to the left leg, which he dragged after him in walking. He was prone to involuntary laughter, and his features were seldom at rest. The senses of sight, hearing, taste, and smell on the affected side were much impaired. After giving a trial to various local and constitutional remedies in vain, and finding that the fourth dorsal vertebra was exceptionally sensitive to percussion, I applied a small blister over the fourth and fifth vertebræ, and with the healing of the raw surface every choreic and paralytic symptom had departed.

CASE 2. *Facial paralysis.* — About the same time a married lady, the mother of two children, consulted me for an attack of facial paralysis, accompanied with ptosis and derangement of vision in one eye, partial loss of taste, smell, and hearing on the same side, with loss of sensation in the integuments of the face and cheek on that side; the third, fifth, and seventh cranial nerves were engaged. In her case the fourth and fifth dorsal vertebræ were painful on pressure, and these only. After fruitlessly trying a variety of remedies then in vogue, I ordered a blister to be applied over the tender vertebræ; this was done, and before the expiration of a week all the motor and sensory functions in abeyance were completely restored.

CASE 3. *Chorea.*—In the summer of 1860 I was called to a case of well-marked chorea in an unmarried female, aged seventeen, her second attack. Her previous illness lasted for six weeks; she had then been under the care of a skilful practitioner, who prescribed cold shower-baths and drachm doses of carbonate of iron. I found her suffering from incessant jactitation of both upper and lower extremities, which seldom ceased even during sleep. Her head and tongue were in constant motion; there was no history of rheumatism or evidence of cardiac disease. Having found the fourth dorsal exceedingly sensitive to pressure, a blister was applied over it for eight hours; it rose well. I did not prescribe any other mode of treatment, and at the end of eight days the patient was restored to perfect health.

CASE 4. *Facial paralysis.* — On June 14th, 1870, Miss P—— called on me. She had contracted facial paralysis by sitting for some time at the open window of a railway carriage. Her mouth was drawn to one side, her left eye was permanently open, tears streamed unchecked from it over the cheek; common sensation and hearing were much impaired on the same side; she put out her tongue very awkwardly, and spoke with difficulty. On examining the vertebral column she shrank with a cry of pain when tapped over the fourth and fifth dorsal spines, over which a blister was applied. I saw her forty-eight hours afterwards, when she showed a marked improvement. Complete recovery resulted in the course of a few days.

CASE 5. *Chorea.*—C. K——, a lad thirteen years of age, was brought to me on Sept. 9th, 1870. He had but recently recovered from a prolonged attack of rheumatic fever, fourteen days after which the present symptoms supervened. He had been treated, his mother informed me, for some time without any benefit as an out-patient at the General Hospital. The left arm and leg, which suffered most from the rheumatic attack, were now the most affected with choreic movements. His eyes, lips, and head were in almost perpetual motion; there was no perceptible cardiac complication. I did not prescribe any medicine, but over the fourth and fifth dorsal vertebræ, which responded as usual to pressure, I applied the ordinary counter-irritant. On the 12th he had acquired control of the left hand, could hold a cup steadily, and perform any manual office freely. On the 19th he was quite well, with the exception of nervous twitches in his face. I then applied a second blister over the same place, and when he visited me on the 26th every abnormal symptom had disappeared.—Second attack: On Jan. 23rd, 1871, the lad had a return of the disease, almost a counterpart of the first attack. I ordered a blister, as before, to the same region, but was disappointed in not discovering any improvement. On the healing of the raw surface, however, I applied dry cupping glasses over it and near it, with great relief; a second application of the glasses completed the cure. I then took the lad into my service. Good fare and suitable occupation established his health, and he afterwards took to seafaring, and has been for some years an able bodied seaman in a coasting vessel.

CASE 6. *Facial paralysis.*—On Feb. 2nd, 1880, a lady called with her daughter, Miss L——, aged nineteen years. The latter stated that when passing from an overheated room into the outer air, then below zero, she suddenly felt a burning sensation in her right cheek, followed by sore-throat. She was then menstruating. On reaching home it was observed that her mouth was drawn to the left side when she attempted to speak or laugh; she was unable to corrugate her eyebrows, to wink with the right eye, or to close it, and when going to sleep had to bring down the right upper eyelid with her fingers. She could not distinguish even the largest type with that eye, and the sense of hearing on that side, and that of taste with the right half of the tongue, and of smell in her right nostril, were almost entirely obliterated. She suffered from epiphora, tears were constantly flowing over the affected cheek; when attempting to masticate, her food remained in the right side of her mouth till relieved by the finger, and she could not clear her mouth of saliva by ordinary expectoration. Common sensation was almost absent on the affected side. Her speech was indistinct, and she could not pronounce any

Digitized by Google

word beginning with a labial. Before proceeding to treatment I invited my friend Dr. Walton Browne to look at the patient, and after he had recognised fully the nature of the case, I demonstrated the presence of spinal hyperæsthesia at the region of the fourth dorsal vertebra, and ordered the local application of a blister. This was done on Feb. 3rd, and at my visit on the 4th we found the patient much improved, especially in the direction of the motor symptoms. At the end of a week all phenomena due to lesion of the portio dura of the seventh nerve had disappeared, while those depending on the fifth and the nerves of special sense were still observable. I now applied a second blister over the same spot, and at the date of its cicatrisation (Feb. 16th) the patient was completely cured. It is worthy of remark that in the progress towards recovery the lesion of the motor nerve took precedence, and seemed to march in a different track from that of the sensory and special senses.

CASE 7. *Frontal neuralgia of the first division of the fifth nerve.*—On May 17th, 1881, Mr. E. M——, aged nineteen, called on me, complaining of neuralgia in the supraorbital division of the fifth nerve, which commenced the day following a thunderstorm, it subsided at night and recurred with violence every day about 10 A.M. He was of a neurotic family, his sister a martyr to hysteria, and his father, under forty years of age, crippled with neuralgia. I at first prescribed five-grain doses of croton chloral and the external use of atropine liniment, with only partial relief. After a week's trial I suspended their use and applied a blister over the fourth and fifth dorsal spines. The next morning there was an abortive attempt at a recurrence of the pain. At the end of a week, however, he informed me that he had completely recovered, and that after the blister had thoroughly risen, with the exception mentioned, he had not experienced the slightest pain.

CASE 8. *Facial neuralgia of the first and second divisions of the fifth nerve.*—Mrs. C——, aged twenty-four, mother of one child, very subject to neuralgia, and at present suffering, and had been for the previous fourteen days, from pain in the left side of the cheek, forehead, and face, called on me on May 26th, 1882. She informed me that this attack appeared twenty-four hours after a peal of thunder. She also complained of occasional pain in the left eyeball and severe pain at the exit of the supraorbital and infraorbital nerves. At the latter place there was a bright-red patch, which was painful and inflamed. The attack came on every day at 10 A.M., and lasted till noon, occasionally returned in the evening, and then subsided till the next morning. At its daily advent she became faint and felt great chest oppression; she was very anæmic and consumptive. Suffice it to say that a blister applied to the usual spot removed effectually and at once all neuralgic suffering, and she continued free from pain for many months afterwards, and as long as she was under my observation.

CASE 9. *Neuralgia of the third division of the fifth nerve.*—Mrs. McM——, aged nineteen, married six months, called on me at 6 P.M. on Nov. 5th, 1882. She complained of intense pain in the first molar of the lower jaw on the left side, the corresponding tooth had been extracted some months before for a similar cause, when immediately this tooth took on symptoms of toothache and began to be carious; the pain extended to the brow and head on the same side, and interfered with mastication. She had not slept for many nights. I applied the vesicating fluid over the fourth and fifth dorsal. Next day she called to say that an hour after its application she began to feel relief, that she fell asleep at 7 P.M. and awoke in the morning perfectly free from pain, which never returned. She was confined on February 14th, 1883.

CASE 10. *Reflex vomiting in pregnancy.*—Mrs. McM—— called on me again on July 17th, 1884, to say that she was pregnant, for the past two months, for the greater part of which time she had been suffering from pyrosis and sickness after breakfast and supper, teeth quite free, she rejects her food after these meals, and is not quite free from sickness in the intervals. On examining the back for the purpose of applying a counter-irritant, the discolouration caused by the previous application was quite apparent. I applied it as before, and I had a message by her husband to say that all gastric trouble had left contemporaneously with the formation of the blister, and up to date of writing she is perfectly free.

CASE 11. *Reflex vomiting of pregnancy.*—On Jan. 10th, 1884, I was consulted by a lady, the daughter of a medical man, for very severe morning sickness that had troubled her for many weeks. She was then five months pregnant of her second child; the excessive nausea and weakness were giving anxiety to her friends. I promised to cure her at once if permitted, but gave her the choice of a small blister between the shoulders or some sedative medicine. She preferred the blister, which I immediately applied, with the usual effect; the sickness never returned, and I attended her in her confinement on May 18th after. She was very grateful for the rapidity and simplicity of the remedy.

CASE 12. *Ozæna and dysmenorrhœa.*—When attending a lady in October, 1842, for an attack of bronchitis, she requested me to prescribe for a grown-up daughter for ozæna, which made her very unhappy and avoid society. Finding a pronounced spinal tenderness of the customary vertebræ, I said I could not promise a cure, but would make the endeavour. I painted the patient with epispastic fluid, with beneficial result. She called to thank me for the cure of the nasal trouble; but, to use her own words, she "was more than astonished at what occurred at the same time." She was then on the eve of her monthly period, which was always accompanied with vomiting and excessive pain, for which her mother prescribed a sedative, to be used in the middle of the night when the crisis arrived. To her surprise she had slept all night, and the potion was untasted in the cup. Since that time up till the present moment all signs of dysmenorrhœa have been absent in her case.

CASE 13. *Facial neuralgia and borborygmi.*—One Sunday in August, 1883, two sisters called on their way home from church. They were members of the choir, and the elder complained that from the neuralgic pain in her teeth and jaws, extending to the throat, she could not join in the psalmody without excessive pain. She requested me to blister her over the fourth dorsal vertebra. I smiled and answered, "Why?" She said, "You long since by that means cured my sister of a similar attack." I complied with her request, and finding evidence of previous blistering on the same spot, she reminded me that when attending her sister for her neuralgic attack I noticed how much she had suffered from borborygmi, and observed that they were evident many yards distant. The application had completely removed that troublesome ailment. I now painted her over the same spot, with the result of banishing at once all neuralgic affection of the dental nerve.

CASE 14. *Pruritus pudendi of pregnancy.*—In the month of November, 1883, I was called on to visit the wife of a mechanic, then in the fifth month of her first pregnancy. I saw her at noon. Her eyes were red with weeping. She informed me that neither herself nor her husband, who was present, had slept for many weeks, on account of the agony she suffered every night from the effects of pruritus pudendi, which then reached its climax, although painful every hour of the day. They had not the luxury of a second sleeping apartment, and the husband was quite worn out in looking at suffering which he could not remedy nor relieve. I promised to do everything possible for her. I did not prescribe either local or constitutional remedies, but applied the vesicant to the usual hyperæsthesic region, and called on the patient a week later. She was then bright and cheerful and most grateful. She said that the blister had risen before the evening, that at bedtime she slept without waking till the morning, that at breakfast time there was a slight return of the annoyance, and a milder attempt next day, but that it had then completely disappeared. She left for the country, and was delivered of a baby in due course without any return of her former trouble.

In thus selecting for the purpose of illustration a few typical examples from my repertory of cases, it is not my purpose to indulge in theoretic speculation or endeavour to account for the physiological action of the topical remedy under consideration. To explain the reason why derivatives applied to a specific area of the cerebro-spinal system are able to control or remove a pathological condition or state of excitation in regions only indirectly or remotely connected with it—whether by producing hyperæmia, and thus removing congestion; whether through the agency of the vaso-motor nerves, inducing contraction or dilatation of the bloodvessels; whether through the sympathetic system, called into action by irritation of the fine network of peripheral nerve distribution, a rational explanation may be given for these previously unrecognised therapeutic facts; whether the curative action of the cantharides is due to its vesicating power or to its stimulating influence on the skin (according to Anstie on the nervous system also), and a neurosthenic tonic like arsenic, which it is said increases the nerve force and restores order to its action when disturbed,—I shall not assume the

Digitized by Google

responsibility of determining. One important feature cannot well be overlooked—the permanency of the cures of neuralgic ailments. Many years have passed and I have not had even in a single case a recurrence of the disorder; and even the case of Mrs. Mc——, where the exciting cause was again in operation, the neurotic affection did not appear in the form of neuralgic toothache, but in reflex disorder from uterine irritation and pneumogastric sympathy.

Belfast.

ANTISEPTIC STEAM IRRIGATION OF FOUL WOUNDS.

BY LEIGHTON KESTEVEN, M.R.C.S.,
LATE SENIOR RESIDENT SURGEON, BRISBANE HOSPITAL, QUEENSLAND.

NOTWITHSTANDING the immense strides surgery has made in the last few years in the pathology and treatment of all the varieties of wounds, I believe I am right in saying that the "foul" wound is still the bane of surgical practice. By "foul" wounds I mean those large, open, suppurating surfaces which, notwithstanding, or from the previous want of, due antiseptic precautions, are so frequently met with. As, for instance, in the sloughing due to severity of contusion, from burns, phlegmonous erysipelas, indolent large ulcers, opening of abscess cavities, operations for necrosis, and in divers other instances too numerous to relate, where we have this objectionable feature—objectionable in hospital, with all due appliances at hand, from the inevitable septic virulence; and objectionable in the private house, from the dirt, the stink, and the repulsive task of dressing to amateur nurses. Apart from and beyond these grounds of objection, too, comes the far greater one to ourselves of the often insuperable difficulty of healing these wounds; in promoting such genetic action of the tissues as will enable them to repair the loss of material and fill up these "horrid chasms." Any plan therefore which will enable him to cope with these difficulties, or minimise them in any degree, may be acceptable to the practical surgeon; and, though not claiming to have discovered any new remedy, I desire to bring before the notice of the profession what I believe to be a new *modus opplicandi* of one we already possess, and which, I believe, supplies a real want. The oil of eucalyptus is the drug to which I refer, and its continuous application in a vaporous state the *modus*. Not exactly in the same condition of spray as in Professor Lister's method, but as a slight practical modification of its use. Briefly, my plan is this. The steam spray charged with a solution of eucalyptus oil (which from its more agreeable or tolerable odour, and, as Dr. John Duncan of Edinburgh says, its perfect antiseptic properties, is preferable to all other antiseptics for this purpose), played at close distance directly on to the wound for long-continued periods, thereby supplying a moister and warmer vapour—steam, in fact—than the spray, and effecting a mechanical cleansing of the wound combined with a thorough antiseptic permeation of the structures. That this does supply a desideratum of treatment I feel convinced by the successful results obtained in its practical application; and I will instance below two or three typical cases, out of the number I have treated with the same results. I conjecture that the very marked good effect which it has on large slowly healing sores or wounds is due to the stimulating effect to the tissues of the direct force of the steam on them at so close a distance, as the vivifying effect shown in the improved vitality of the part manifests itself so soon after its application. I can only compare this local effect to the constitutional stimulus of the morning shower bath on the man with jaded nerves.

The first case in which I tried this was one of excision—for bone disease—of the entire phalangeal and metatarsal bones, with the third cuneiform, and greater part of the cuboid. The wound was brought together by sutures, but owing to the previous destruction by disease (supposed syphilitic) of the superficial tissues, and the impoverished state of the whole foot, the meagre flaps would not unite, and a deep, gaping wound was left in which abundant sloughs formed, with a fetid, sanious discharge. Various different dressings were applied, always under the eucalyptus spray, with little or no good effect; till it occurred to me that I might by a sort of "steam irrigation" cleanse away a good deal of the superabundant sphacelated tissue. I therefore brought the nozzle of the spray apparatus to within an inch of the wound and turned it on at full pressure for over an hour. No pain whatever was caused by this measure; indeed, whereas the patient had been in acute pain before he said that it was soothed almost immediately by the pleasant warmth of the jet; the surface of the wound being cleared of a very large proportion of the débris, which now lay in a pool of the condensed steam and spray in a mackintosh put under his foot during the dressing. Seeing the good effect of this, I continued it twice daily for at least a fortnight, during which the improvement was most marked. The cavity, which had exhibited nothing but lazy sloughing before, assumed a healthy aspect, and went on filling up rapidly, and I only found it necessary to dress it once daily. All the fetor was gone, and the sanious discharge was replaced by healthy pus in moderate quantity. The very large loss of cutaneous tissue which had occurred by sloughing retarded considerably the closing of the wound, though it still retained its healthy condition, and it was only by constant drawing of the sides together by adhesive plaster that it was eventually healed, after a stay in hospital of nearly a year after the operation. He has now, however, a sound and fairly serviceable foot; and he most undoubtedly owes his having any at all to the timely aid of the "steam irrigation." I ought to say that I plugged the wound each time after the steaming with lint soaked in carbolic oil containing 1 to 20 of oil of eucalyptus.

W. K—— was brought into the hospital with a crushed foot, the wheel of a loaded goods waggon having gone over the instep. There was great laceration and contusion, the dorsum being laid almost bare to the bone, and the foot literally burst open at the outer side from the base of the little toe to the heel, almost entirely detaching the sole of the foot; indeed I could put four fingers between it and the tarsal bones. The first two phalanges were torn from the tarsus, the ligaments of the tarso-phalangeal joints being entirely gone, and the first phalanx of the big toe was fractured longitudinally. The bases of the metatarsal bones protruded from the wound. A hopeless case enough in all conscience for conservative surgery, but the lacerated condition of the wound prevented any considerable hæmorrhage, and, as he was a young, healthy, temperate man, I replaced the metatarsal bones as far as possible, put in sutures where necessary, and dressed it with the carbolic-eucalyptic oil under the spray. The greater portion of the skin of the dorsum, however, and a large part of the side wound sloughed, and the whole was looking utterly intractable when I brought the steam irrigation into play. The effect was the same as in the previous case, and after a long and naturally tedious recovery, he is now at his work again as a railway porter. Curious to relate, he has serviceable good joints in both the injured toes that were torn away. At this time, some eighteen months after the injury, he can walk well on the foot.

In an operation for necrosis where I removed the whole of the front of the tibia leaving a deep trough of bone, where there was every reason to believe the disease was tertiary syphilis of twenty years' standing, the same favourable results followed its application. This was in private practice, and I simply took my spray apparatus to the house, instructed my patient in its application, and left the dressing to him.

A horribly stinking varicose ulcer in a woman aged forty, with a syphilitic history, treated with the usual constitutional remedies, made most rapid progress to recovery after being open for the previous five years.

The advantages I claim to be derived from this very simple modification of an acknowledged plan of treatment are:—(1) Mechanical but gentle and efficient cleansing of foul wounds; (2) ease of pain; (3) obviation to a large extent of the disagreeables (in household cases) of dressing; (4) perfect deodorisation; (5) undoubted acceleration of the reparative process; (6) the most important but usual effect of antiseptic dressing, germ destruction, more thoroughly by greater permeation.

Brisbane, Queensland.

THE Sheerness Local Board of Health have decided to lay out the twenty acres of land they recently acquired on lease from the War Department as a recreation ground for the inhabitants. The Local Governmen Board have been asked to sanction a loan for the purpose.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

GUY'S HOSPITAL.

COMPOUND DEPRESSED FRACTURE OF THE RIGHT PARIETAL BONE; TREPHINING AND RECOVERY SO FAR THAT THE PATIENT FOR SOME WEEKS WAS RUNNING ABOUT THE WARD; DEATH FROM CEREBRAL ABSCESS AFTER HEALING OF THE WOUND; REMARKS.

(Under the care of Mr. R. CLEMENT LUCAS.)

FOR the report of this case we are indebted to Mr. E. A. FARR.

G. R——, a baker's boy, aged twelve, was admitted into the Accident Ward on Jan. 23rd, 1884. At 5 P.M. he was walking in the street during a very strong gale, when a tile fell from the roof of a house, striking him edgeways on the head and knocking him down. He was sick on the way to the hospital, but did not lose consciousness.

On admission at 5.30 P.M. an incised wound existed above and in front of the right parietal eminence, two inches in extent from before backwards, the bone being bare, and a depressed fracture could be distinctly felt. The patient was perfectly sensible, and able to walk into the ward without assistance.

At 8 P.M. Mr. Lucas trephined. The wound was enlarged by extending it downwards to the extent of an inch and a half. The side flaps were then held back, and a circular trephine saw was used near the seat of the depression. Whilst a circular piece of bone was being raised, a large portion of bone, one inch and three-quarters by one inch, came away with it; there were three other pieces, about a quarter of an inch in extent, also removed, the internal table being splintered, so that after all the bone had been removed a hole, two inches in length and an inch and a quarter in width, was left. A little venous bleeding occurred from a puncture of the superior longitudinal sinus, but it was easily controlled by digital pressure. The dura mater was not elsewhere torn or opened. The flaps were brought together with silver wire sutures, and gauze dressings were used, and an ice-bag was put on the back of the head after the operation. He was allowed a pint of milk during twenty-four hours. 10.30 P.M.: The patient lies on his side with his legs drawn up and his thighs flexed on the abdomen; he is perfectly sensible, and answers when spoken to by his friends, but is disinclined to talk. Temperature 100°; pulse 120.

Jan. 25th.—Pulse 134, feeble and rapid. Skin hot and pungent. The right eyelid is very much swollen and discoloured, extending upwards to above the eyebrows, but no conjunctivitis. He is very drowsy, and complains of great pain at the back of the head. Has no paralysis of his limbs. Temperature 102°; respiration 36. Wound dressed, the spray being used every day.

26th.—Head very painful. All the sutures were taken out at 2 A.M., and a large quantity of pus syringed out; there is great tenderness over the portion where the dura mater is exposed.

27th.—Temperature 100°; pulse 120. Discharge soaks through all the dressings; wound dressed three times a day. Throbbing of temples and pain at back of head; œdema of eyes less; movement of limbs perfect; speech clear, but he whines a great deal. A slough the size of a walnut taken away from the wound, which is now sloughing at the lower part. Allowed another pint of milk a day, as he says he is "starving." Ten grains of bromide of potassium, with chloral hydrate, were given on account of restlessness.

28th.—Slight oozing of blood from ears and nose. Cannot bear ice-bag on his head. This morning the movement of the left leg was slightly impaired, but this passed off before the afternoon. Still whines and groans continuously, and does not get any sleep. Ordered twenty grains of bromide with a drachm of syrup of chloral every six hours.

30th.—Patient slept four hours last night; there is a wonderful change this morning. He is sitting up in bed smiling, and says he is quite well and has lost all his pain. Temperature 98·4°. Granulations have sprung up at the edges of the wound; the bone is dotted over with minute red spots. Pulsation can be seen at the part where trephining was performed. There are about three drachms of laudable pus discharged. Dressed under spray once during the day.

31st.—Edges of wound brought close together with the aid of strapping.

Feb. 1st.—Pulse 104; temperature 98·4°. Two blebs have appeared, about three inches in extent, covering the whole of the heel and internal malleolus of the left foot; they are superficial, of a greenish colour, with red edges and a raised centre. They were opened with a pair of scissors and an ounce of pus let out, and then syringed with carbolic lotion (1 in 60) and dressed with strips of carbolic lint.

4th.—Put on fish diet. Temperature normal.

6th.—The bottom of the wound is covered with healthy vascular granulations extending from the edges to the centre; about an inch by a quarter of an inch of bone is now exposed. Has slight headache. Temperature 99°. The blebs on his foot have healed.

10th.—Wound dressed every day; much the same condition. Sleeps fairly well, but still complains of headache. Temperature 99°.

15th.—Pupils slightly dilated; still has headache and throbbing in the right temple and ear.

24th.—Dressed every day. The whole surface of the exposed bone is now covered in with healthy granulations, and skinning over from the edges. There is pulsation over an area of one square inch at the lower edge of the wound. The granulating surface measures two inches and a half in length by an inch in breadth.

March 13th.—The patient had been eating some figs, which made him sick; he complained of intense headache, so he was kept in bed. This occurred after a tea-party to which he was invited.

17th.—Headache, accompanied with shooting pains; he groans very much, and is unable to localise pain; when spoken to answers cheerfully. Temperature 99°.

18th.—Tongue coated with moist fur; complains greatly of frontal headache; restless; sick twice during the night. Milk and ice ordered. Bowels acted well after taking one ounce of castor oil.

21st.—Bowels constipated. Given ten minims of extract of cascara sagrada with twenty minims of syrup of tolu twice a day.

23rd.—This morning he is exceedingly restless, tossing about in bed, throwing off the ice-bag from his head, and screaming out that his head aches. Three grains of calomel were given.

25th.—Bowels well open. Temperature 98·2°; pulse 78, hard, slow, and irregular. He has internal strabismus of left eye; opening of eyelids painful; pupils widely dilated and insensible to light. Eyes examined by ophthalmoscope. Right eye: inner two-thirds of optic disc blurred; veins swollen and turgid. Left eye: veins of left optic disc swollen. Internal strabismus of right eye.

26th.—Right optic disc completely blurred; left optic disc at upper and inner part blurred. Patient very restless.

27th.—Lies quietly in bed, dull and heavy, but answers questions readily. No headache, but pains at the back of the neck. No sickness since the 19th.

28th.—Passes his motions involuntarily under him. Double internal strabismus from paralysis of external recti. Very weak, and much thinner. Intense pain at back of neck below the external occipital protuberance, and extending down back; a small Leiter's coil put on. Ordered two ounces of brandy.

31st.—Pains in the limbs and back; right arm more than left. Pulse 62, weak and irregular. Lies in bed quietly at times, calling out in shrill tones.

April 2nd.—Difficulty of breathing, during expiration uses his diaphragm strongly.

3rd.—Slightly delirious. Temperature 98°. Died at 11.45 P.M.

At a post-mortem examination the brain was found to weigh 63 oz. An abscess about the size of a hen's egg was seen in the right frontal lobe, containing about two ounces of pus; it was situated immediately beneath the seat of trephining, one-eighth of an inch from the surface of the brain. Double optic neuritis was present, but no meningitis. The opening in the skull was completely covered by skin and dura mater. All the other organs were healthy.

Remarks by Mr. CLEMENT LUCAS.—This boy lost his life through the gale which swept over London on the 23rd of January. A tile was blown off a house as he was walking in the street and it fell edgeways, an angle striking his head and driving in the bone. Although the injury had produced no symptoms of compression there was a sharp angular depression with separated fragments, calling for trephining. These were removed, and a small punctured wound of the longitudinal sinus was found on elevating the bone. The hæmorrhage from this source, though considerable, was readily stopped by digital compression. Some suppuration and a little sloughing of the lacerated and contused scalp followed, but when this slough separated and the suppuration had subsided, the case progressed most favourably, the wound closing in by granulations. A week after the operation his temperature had fallen to normal, and then for several weeks he was regarded as out of danger and soon was allowed to be about the ward. During this time he occasionally complained of headache, but was intelligent and happy. On March 13th, seven weeks after the injury, he was allowed to attend a tea-treat given in the hospital, and in the evening ate several figs given him by another boy. He was afterwards very sick, and complained of intense headache. The attack at first appeared to be directly occasioned by the indiscretion in diet, but the subsequent course of events seemed to indicate that it brought to light symptoms of disease which had probably been slowly progressing. However this may be, the case proves what is no new fact, that for a long time after a head injury a carefully restricted diet should be persevered in. The pain in the head suddenly became intense, causing him to groan and occasionally to scream out with agony. It was chiefly confined to the occiput and back of the neck, and as it was soon followed by squint and signs of optic neuritis. These symptoms were taken to indicate basal meningitis. There was, however, scarcely any rise of temperature, and his intellect remained for a long time quite clear. Meanwhile the wound had healed, and there was no indication of anything amiss in the neighbourhood of it. He was carefully watched for the onset of any paralysis, to assist in localising the mischief, but, except the affection of the eyes, none occurred. He grew gradually weaker and thinner, then passed first urine and afterwards fæces involuntarily, and thus faded out without developing any paralysis of the extremities. The post-mortem examination revealed an abscess situated in the substance of the brain, not reaching quite to the surface nor extending to the ventricles, but in a position which could have been reached by a trochar and cannula plunged through the trephine opening. It is, perhaps, to be regretted that this was not done, but how the abscess cavity could have been drained would still have been a question of interest. Inversion of the body would seem to be the only way unless some syphon arrangement were contrived. It is probable that our prejudice against adopting the inverted position for drainage in head injuries is largely due to preconceived notions and the imbuement of popular ideas in our surgical practice. Still he would be a bold man who carried out in this way the principle of letting an abscess drain at its dependent spot. We must confess to having left this case to die without opening the abscess, but in another case where symptoms of an indefinite kind supervene some time after an injury we should be tempted to explore deeply though our wounds were healed, and though the symptoms were misleading as to the situation of the disease.

LIVERPOOL ROYAL INFIRMARY.

IMMEDIATE GANGRENE OF THE UPPER LIMB, PRESERVED ASEPTIC, AND SUCCESSFULLY AMPUTATED AT THE SHOULDER-JOINT SIX DAYS AFTER INJURY; RECOVERY; REMARKS.

(Under the care of Professor RUSHTON PARKER.)

HUGH W——, aged fifty-three, fell under a railway engine at Ormskirk on the evening of Sept. 1st, 1883, in a state of intoxication, while trying to evade the officials of the train in which he had been travelling without a ticket. He was taken to the Ormskirk Union Hospital, under the care of Dr. Anderton, who brought him to the Liverpool Royal Infirmary the following evening.

When seen shortly afterwards by Mr. Rushton Parker, in the presence of Dr. Anderton and another medical man from Ormskirk, the patient was cold and depressed with a weak pulse and an air of indolent dilapidation. The right upper limb lay helpless and cold. The shoulder and upper arm were swollen and ecchymosed and a little excoriated, but the rest of the skin was pale white and nowhere severed through. The humerus was obviously broken to splinters in its upper third; the artery, presumably plugged in the axilla, whether severed or not from the limb, besides being cold was pulseless below. The nerves were apparently bruised, if not divided, for all muscular and sensory power were gone, and the wrist and fingers were rigidly flexed. His cold and listless condition was, it was thought, unfavourable for the immediate respiration of anæsthetic vapours, and consequently for the performance of a serious operation; and even if this were survived the subsequent occurrence of early blood-poisoning was thought likely to be most difficult to prevent. The unbroken state of the skin made it appear probable that the injured tissues and extensive blood extravasation could with simple precautions be maintained uncontaminated, and consequently harmless, until he should sufficiently recover his strength to be submitted more hopefully to the inevitable amputation. So the opportunity thus afforded of gaining time was gladly seized. The skin of the limb, shoulder, and adjacent trunk was accordingly submitted to prolonged soaking with a hot watery solution of carbolic acid, varying from 2 to 5 per cent., after which a large gauze dressing was put on around the chest, enveloping the limb and immovably fixing it in the flexed position to the side, after the Listerian method of dressing an excised breast. The patient was put to bed, and daily improved in every way, feeling no inconvenience from the injured limb. Three days later he was taken into the theatre for amputation, but on inspection of the limb there appeared to be no occasion for hurry, and so it was decided to put off the operation two more days, for further improvement in the patient's strength. His complexion was now clear, his colour good, and his spirits revived. The limb was warm from contact with his body, but clammy and evidently dead. A slightly leaden hue had come over it up to the upper third of the arm, where a line of demarcation appeared in course of formation. But no black, green, or other colouration affected the skin, which appeared perfectly preserved throughout. A fresh application of wet gauze was applied direct to the excoriated parts, and the dry portions of the gauze dressing were replaced.

On the sixth day after injury amputation was performed under the influence of ether, the patient being quite well and in good spirits. By this time the line of demarcation had become more distinct, but without any inflammatory or ulcerated margin in the living skin. The lividity was more intense, but there was no trace of the dark colouration that occurs in exposed gangrenous parts. No precautions were taken to prevent hæmorrhage on account of the obvious plugging of the artery, so the operation was one of entire simplicity. The limb was grasped at the elbow with one hand, and severed with a short amputating knife held in the other by two long incisions from the angle of the scapula to a point on the chest near the nipple. The first incision through the integuments passed pretty much along the axillary border in the line of the teres and pectoralis major, curving across the inner side of the limb over the insertion into it of these muscles, as the elbow was held high up in the abducted attitude of the shoulder-joint. The other incision passed across the outer side of the limb, somewhat conforming with the lower margins of the deltoid muscle, joining the previous incision some distance from each end of it. A gush of bloody serum escaped from behind at the first puncture; the incision of the integuments almost sufficed to sever the limb, which was now found attached only by three of its large nerves, which were at once divided. The artery was found severed, and soundly plugged for an inch or two. The head of the bone was cut out of its glenoid cavity, and a few bleeding points thus opened were tied, the previous detachment of the limb having occurred at the point of fracture low down in the surgical neck. A similar dressing to that previously employed was placed upon the stump after putting in sutures and wide long drainage-tubes. Putrefaction occurred in the dressings after a few days, on account of which the sutures were all removed and every corner of the wound washed out daily with carbolic lotion, and freely smeared with eucalyptus petroleum ointment. A few sloughs at the edges of the flaps were clipped by degrees away, and eventually the putridity ceased. But the constitution of the patient never suffered in the least, no absorption of putrid materials having occurred. He remained two or three weeks in bed,

Digitized by Google

and left the hospital at the end of two months, all being healed except an exposed tendon above the glenoid fossa. He returned to Ormskirk Union, where he remained till the end of the year.

On January 30th, 1884, he came over to Liverpool. A pouting granulation still remained in a corner of the scar. This was snipped off at once. The following day he appeared at the Medical Institution, and in a few days more he returned to Ormskirk, the spot having entirely healed.

Remarks.—In cases of extensive injury, especially with rubbing-in of dirt, and even without that in the presence of much bruising, the surgeon is naturally anxious to cut away, as soon as it is safe practically to do so, all tissues in which subsequent putrefaction is otherwise certain to occur. Temporary disinfection of wounded parts, when effectually possible, is obviously the only alternative to amputation in the case of hopeless destruction of tissues; and this expedient was in the present instance as easy of execution as could be wished. Had the tissues been exposed, their disinfection would have naturally been advisable, but would have been difficult, if not impossible; and the alternative amputation might have been considered a duty at a period too early or too late for the patient's safety. As it was, valuable time was gained, and the hour of amputation safely postponed; for the extensive ecchymosis and deep dead parts were not considered likely to undergo decomposition, while the dead skin was artificially preserved by superficial disinfection. At the moment of amputation the severed limb was in a state of perfect preservation throughout. The whole of the extensive ecchymosis and serous effusion remained similarly undecomposed, as evinced by freedom from turbidity and from loss of colour. The injured tissues of the stump manifested no sign of acute inflammation, except in one corner of the axilla, where at the moment of removal about a teaspoonful of purplish-grey puriform sanies was observed; and on the excoriated patch of skin over the scapula, where a little lymph and serous exudation, with the orange pigmentation that indicates one of the forms of micrococcous growth, showed the commencement of fermentative irritation. It is probable that in a few days more the focus of internal suppuration would have mixed with the adjacent liquid effusion, while the superficial decomposition of the skin, as it was probably spread by direct infection to the dead portions of skin left on the margin of the wound, would have had an unlimited extent of dead tissues in which to revel had the operation been further postponed.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Cystic Disease of Cerebellum, Kidneys, and Pancreas.—Intussusception in an Adult Male.—Simple Ulceration between Trachea and Œsophagus.—Tumours of Soft Palate.—Congenital Hydrocele of Spermatic Cord.—Infiltrating Fibroma of Thyroid.

AN ordinary meeting of this Society was held on Tuesday last, Mr. J. Whitaker Hulke, F.R.S., President, in the chair. An extraordinary living specimen of congenital deformities was exhibited by Mr. F. Treves.

Dr. PYE-SMITH read notes of a case of Cyst of the Cerebellum in a young man aged twenty-seven. The symptoms lasted only three months before death; they were vomiting, severe occipital headache, vertigo, double optic neuritis with retinal hæmorrhages in the right eye; there was no paralysis; no spasm and no convulsions. The patient gave a history of injury; the diagnosis made during life was abscess in the occipital lobe or in the cerebellum. Death was due to asphyxia. At the autopsy a simple serous cyst was found in the left lobe of the cerebellum; it was the size of a large walnut. There was passive effusion into the lateral ventricles, but no sign of meningitis. There were several small cysts in the pancreas and more numerous cysts in both kidneys, but no other signs of disease. Reference was made to other cases of simple serous cysts in the cerebellum which were not hydatids nor due to absorbed blood-clot, nor degenerated sarcoma or glioma. Reference was also made to a case of cystic disease of the liver and kidneys published by the author in the Pathological Transactions, vol. xxxii. (vide THE LANCET, Dec. 24th, 1881).—Dr. NORMAN MOORE referred to specimens of cystic kidneys in which the tissue between the cysts was perfectly healthy. In some cases he thought serous cysts developed in the meshes of the connective tissue of the various organs.—Dr. W. B. HADDEN spoke of a case which he had published. It was that of a woman, aged twenty-eight, in whom the symptoms of cerebellar disease—vertigo, occipital headache, staggering gait, vomiting, optic neuritis, and later on delusions—were well marked. There was a tumour in the left cerebellar lobe of the nature of a simple serous cyst. A history of injury was obtained.—Dr. CARRINGTON said the kidneys were examined microscopically for Dr. Pye-Smith and found to be healthy.—Dr. HALE WHITE referred to cases published by him in the Pathological Transactions for 1884, in which the kidneys, liver, heart, lungs, and brain all contained cysts of which the contents were gelatinous fluids. He came to the conclusion that the cysts were due to vacuolation of the cells; as a rule the cysts in the kidneys were the result of dilatation of the tubes.—Dr. PYE-SMITH, in reply, said it was possible for the cysts to originate in natural areolæ of the connective tissue, but he rather thought that the cysts were dilatations of the Malpighian capsules, as in the case shown before the Society in 1881.

Dr. LANCHESTER read a paper on a case of Intussusception in an adult male. The patient was a labourer, aged thirty-seven, who enjoyed good health, but had a little diarrhœa on February 7th, which continued a few days, the motions were bloody, and there was some tenesmus on the 15th. He was admitted into hospital, when the diagnosis of intussusception was made; the mass of diseased bowel could be felt per rectum, but the invaginated portion was too firmly impacted to give any hope of effecting reduction. Vomiting and hiccough began twenty-four hours after admission. The feeling of firm impaction, and the duration of the case, were the reasons for not performing abdominal section. Left lumbar colotomy was performed with a view of giving temporary relief, and in the hope that the intussuscepted portion might slough and come away. The patient died from peritonitis forty-eight hours after the operation. The specimen showed an invagination of the gut about three inches and a half in length, but the normal relations could not be restored whilst *in situ*; the firm impaction seemed partially dependent on the contracted mesocolic attachment. The disease may have been of long standing, whilst the symptoms were probably due to a recent strangulation.—Mr. JOHN CROFT asked whether both the muscular and the mucous coats were invaginated. He presumed the whole of the coats were involved.—Dr. SAMUEL WILKS said apparently all the coats of the intestine were invaginated; he had seen but two cases of intussusception in adults, and he considered the case as a remarkable and unique one.—Mr. R. J. GODLEE said that he had seen one case in which there was a tumour on the inner aspect of the bowel. What was the object of opening the descending colon? It was to be regretted that the case had terminated fatally, since it would have been interesting to see how far the symptoms would have subsided, for the nipping of the gut would have remained whilst the obstruction to the passage of fæces was removed.—Mr. W. HULKE referred to a case recorded by Dr. Coupland in which only three or four feet of small intestine had not been intussuscepted.—Dr. LANCHESTER, in reply, said, with regard to the propriety of operating, he had determined, by rectal examination with the hand, that the intussusception had begun at the lower end of the sigmoid flexure, and so he felt sure that he would be above the point of obstruction.

Dr. CARRINGTON read a paper on a case of Simple Ulceration establishing a communication between the Trachea and œsophagus, and setting up purulent bronchitis, with "sloughy" broncho-pneumonia. The patient was a man, aged twenty, who was admitted into Guy's Hospital on July 11th, 1884, under the care of Mr. Bryant. On June 19th, having opened a cask containing carbonate of ammonia, the patient was nearly suffocated by the fumes; half an hour later he could not swallow the first few mouthfuls of tea; two hours after the patient was only able to swallow some of the contents of a glass of beer, but the small quantity returned through the nose. Some hours after he vomited during a fit of coughing a small quantity of "matter and blood." After this event he was unable to swallow anything. He was fed by nutrient enemata. On admission to the hospital in July there was an ineffectual attempt to pass a bougie, and on a repetition of this attempt on July 22nd the bougie passed into the trachea. There were high fever and the

Digitized by Google

signs of broncho-pneumonia. The pulmonary symptoms increased in severity, and the patient died on July 23rd. At the autopsy a fistulous communication was discovered between the œsophagus and trachea, and situated two inches below the level of the cricoid cartilage. The fistula was of an elongated form, and was longer on the œsophegeal than on the tracheal side. The margins of the opening showed no trace of thickening or malignant disease. The bronchial tubes were acutely inflamed and superficially excoriated, these phenomena being probably caused by the passage of swallowed matters into the trachea. Many patches of broncho-pneumonia were in a softened and sloughy state. There were no signs whatever of malignant disease, tubercle or syphilis. Dr. Carrington remarked on the obscurity of the affection, both as to its nature and the site of its origin. He thought that a case which he had recently seen might throw some light upon it. In the œsophagus of an individual who died of some independent malady, a scar was seen side by side with a small diverticulum. Might the lodgment of some material in such a diverticulum lead to suppuration and abscess, from which perforation of the trachea might ensue. The violent fit of coughing induced by the fumes of ammonia might have caused the final rupture of such an abscess as in the case under notice; the ejection of "matter and blood" by the patient some hours after the onset of the illness was of much interest.—Dr. S. WILKS spoke of a case recorded in the Pathological Transactions many years ago, in which a hole existed between the trachea and œsophagus, and in which there was no apparent malignant disease. A lupoid infiltration was spoken of, but was of doubtful existence.—Mr. A. BOWLBY said that he had seen an instance of ulceration of the œsophagus which seemed simple, but in which there was a cancerous growth in the kidney.—Mr. H. T. BUTLIN remembered the case referred to by Dr. Wilks, and from an examination of the reports of the Morbid Growths Committee, he concluded that the specimen was one of epithelial cancer.—Dr. ANGEL MONEY referred to a case which he had examined after death, with Dr. Wight of Holloway. To the naked eye there seemed to be no infiltration of the walls of the fistula, though there was no doubt of the malignant nature of the case.

Mr. TREVES exhibited two cases of Primary Tumour of the Soft Palate. The first patient was a man aged sixty-eight. The tumour occupied the whole of the left side of the soft palate. It was first noticed eight months before the man came under treatment. A precisely similar growth had been removed from the same part of the palate thirty-seven years ago by the late Mr. Luke. Mr. Treves ligatured the left common carotid, and removed the growth, together with the whole of the left half of the palate. The tumour had been examined by Mr. Eve, and proved to be an alveolar sarcoma. The mass was faintly encapsuled, and there was no glandular implication. The patient made a rapid recovery. The second patient was a man aged fifty-six, who presented a tumour the size of a chestnut on the right side of the soft palate. It had been first noticed two months before the man's admission into the London Hospital. Mr. Treves ligatured the right common carotid, and removed the tumour, as in the previous case. The patient made an excellent recovery. Mr. Eve had reported that the tumour was an adenoid carcinoma. Mr. Treves alluded to the great rarity of primary tumours of this part. He had found isolated records of all forms of connective tissue tumour in this region, of adenoid cancer, of so-called myomata, of vascular growths, of pure papillomata, and of dermoid cysts.—Mr. GODLEE had seen two cases in which both tumours shelled out easily from the soft palate; he had also met with two cases of papilloma of this region.—Mr. HULKE thought there could be no doubt that these tumours were excessively rare. He had notes of three cases.—Mr. BOWLBY thought both tumours were of an epithelial type, and had an alveolar stroma. He failed to see any difference between the cells of the one and those of the other.—Mr. TREVES thought that the history would hardly concur with that of carcinoma; no recurrence had taken place for thirty-seven years.

Mr. JOHN POLAND showed a specimen of Congenital Hydrocele of the Spermatic Cord taken from a child aged three years and a half. There was a swelling about the left side of the scrotum, which had been there since birth and had gradually increased in size. The tumour was said never to have disappeared or diminished in size at any time and crying did not increase its size. The patient was admitted into the North-Eastern Hospital in 1881 with acute peritonitis following the tapping of the hydrocele three days previously. The signs of acute suppurative peritonitis were seen at the autopsy. The peritoneum was full of pus; the sac of the hydrocele below communicated freely with the peritoneal sac. Its wall was much thickened by inflammatory material; the inner wall was shaggy from purulent lymph and the cavity contained sero-pus like that in the abdomen. The tunica vaginalis at the lower end of the sac was intimately blended with it; the smooth and glistening lining of the tunica vaginalis showed no traces of inflammation; the partition between the hydrocele and the tunica was firm and thick. The sac of the hydrocele extended upwards two inches and a half into the external abdominal ring, where it became somewhat narrowed at the internal ring; its constricted upper orifice (one-eighth of an inch in diameter) reached into the abdomen, with a finger-like process of peritoneum round its circumference. The cord was placed on its posterior aspect closely connected with its posterior wall. The specimen, the only one of its kind, showed well the process of formation of hydrocele of the cord from the funicular process of the peritoneum remaining unobliterated. It was called congenital, meaning a hydrocele of the cord still having a communication thereby with the abdomen above. Nearly all so-called encysted hydroceles of the cord have this same mode of origin, but the term was a convenient one. The specimen was an exceedingly rare example of a very early condition—namely, partial closure of the process of peritoneum at the internal abdominal ring.

Mr. BOWLBY read a paper on a case of Infiltrating Fibroid Tumour of the Thyroid Gland. The patient was a woman, aged forty-two, who first began to suffer three years before death. There was a history of much excitement and worry. Dr. Conolly made out that the thyroid gland was slightly enlarged in 1881, and in October, 1882, the enlargement had become greater. It was a hard, painless growth, and caused no dyspnœa. An ointment of iodide of mercury was employed with but little effect. Gradual enlargement laterally and vertically took place, and the consistence of the tumour became still more stony. Dr. Felix Semon saw the patient in April, 1883, and considered the disease to be malignant. The growth pressed upon the trachea and narrowed the calibre of that tube; the left vocal cord was fixed in the middle line from paralysis of the abductor. Attacks of dyspnœa then began to occur, and had become more frequent by the end of October, 1883, and the patient suffered a little from dysphagia. So the case went on till November 23rd, when the patient's life was evidently in peril from dyspnœa. She was admitted into St. Bartholomew's, and it was then not possible to recognise the natural structures of the neck. Tracheotomy, performed by Mr. T. Smith, was followed by temporary relief, but death followed. At the post-mortem examination the large new growth was found to be of a similar shape to the thyroid gland, and had a fibrous look on its cut surface. The outline of the tumour was ill-defined below, behind, and laterally; the nerves, veins, and arteries of the neck were included in the tumour; the trachea was compressed laterally and in front, and in places infiltrated by the new growth; there was no ulceration of the trachea; the aorta and all its branches were incorporated in the tumour, to which the apex of the left lung was adherent though not infiltrated. Microscopical examination showed the tumour to be entirely fibrous throughout; there was no disease of the surrounding lymphatic glands. The rarity of fibroma and the infiltrating manner of the growth were the interesting points. The tumour was malignant in its clinical characters because of its infiltrating nature; the slow process of growth and the absence of secondary deposits and glandular affection were noteworthy features.—Mr. BUTLIN had come to the conclusion that the case was one of malignant tumour on account of the invasion of all the tissues with which it had come in contact. It was not an innocent tumour except in histological characters. Hard carcinomata might become entirely fibrous, but the outlying parts of the growth should show spheroidal cells. Was the tumour sarcomatous? Rindfleisch looked upon fibromata as sarcomata, placing them after the spindle-celled variety. Mr. Morris and Mr. Haward had shown curious specimens of disease of the thyroid, which proved that this ductless gland presented many singular pathological puzzles for consideration.—Dr. NORMAN MOORE said that Dr. M. Baillie had observed a slight degree of ulceration in the œsophagus in cases of carcinoma of the thyroid body.—Dr. GOODHART referred the specimen to those classes of cases in which

Digitized by Google

infiltrating fibrous forms of growth were met with in the peritoneum and ovary.—Mr. BOWLBY, in reply, considered that, in the manner of its growth and in its composition from fibrous tissue, the tumour was sarcomatous and malignant.

The following card specimens were shown:—Mr. Treves: Epithelioma of Bladder with Renal Calculus. Mr. Bowlby: Fistulous Communication between Bladder and Rectum. Dr. Paddison: Charcot's Disease. Dr. Norman Dalton: Tumour of Bladder and Surgical Kidneys; Chronic Orchitis; Cylindrical Epithelioma of Sigmoid Flexure, in which the new growth in the liver was associated with tubercle. Dr. Edmunds: Casts and photograph of Hypertrophy of Tibia. Mr. Hudson: A new Ether Microtome.

The following recent specimens were exhibited:—Dr. Carrington: Red Atrophy of Liver. Dr. Pringle: Fatal Typhlitis after Enteric Fever.

CLINICAL SOCIETY OF LONDON.

Charcot's Joint Disease.

THE meeting which took place on Nov. 28th, with the express purpose of discussing the nature of Charcot's joint disease, was crowded to overflowing. Living specimens, casts, drawings, photographs, and specimens, illustrating the morbid anatomy of the disease in question, were exhibited in all parts of the rooms in which the Society meets. The great success of the gathering was largely due to the activity of the most executive portion of the council, the president and hon. secretaries, Sir Andrew Clark, Dr. S. Coupland, and Mr. Rickman Godlee. The proposal to adjourn the discussion to the next ordinary meeting was put to the meeting by the President and carried.

Mr. Morrant Baker having read a summary of the paper which had elicited the discussion at the previous meeting, and Mr. Godlee an abstract of the views of the speakers who had joined in the discussion, the President called on Mr. Barwell, who had moved the adjournment of the debate.

Mr. BARWELL referred to the state of knowledge concerning the neural origin of joint disease, and thought that we knew but little of the real nature of acute, chronic, and gonorrhœal rheumatism. There was great evidence to show that arthritis deformans originated in some nervous injury which was not the same as the nervous injury in locomotor ataxia. He believed the two diseases to be separate, though both might be due to neural affection. It was necessary to compare the anatomical and clinical appearances, and he ventured to believe that these were more diverse than they at first sight appeared to be. Taking, for example, the elbow-joint of a case of Charcot's disease, the head and neck were almost entirely worn away, as were also the ulna and internal condyle of the humerus; the changes were not the same as we find in chronic rheumatic arthritis. He had never seen a joint possessing these appearances when the disease was arthritis deformans. The marginal hyperplasia, so strongly marked in chronic rheumatic arthritis, was absent in Charcot's disease. The interstitial atrophy and porcellanous deposits with the polished surfaces of arthritis deformans, together with the false bodies, of which as many as fifty may be found, were marked features of chronic rheumatic arthritis. Of the fibrous degeneration of the articular cartilage he said it was a very peculiar one, and he had never seen it in any other disease than arthritis sicca. The characters which marked the clinical course of Charcot's disease, the painless manner of its onset, and the rapid swelling of the whole limb, as well as of the diseased joint, were never observed in arthritis deformans where the hydrarthrosis was of gradual appearance when it occurred. The amount of movement in Charcot's disease and the large size of the joints which were usually affected were other characteristics; whilst the adduction of the hand was never met with.

Sir JAMES PAGET said he had listened with pleasure to the able exposition of Mr. Morrant Baker, and he agreed closely with him upon nearly all his points. And first, as to whether Charcot's disease was a new disease. In settling this question we should have to consider the positive and negative aspects. If we could prove that it was not old, that would be all that could be possible under the circumstances. Many things that happened in our environment we were totally unconscious of, and so it was easy to understand how disease might have been overlooked in the past. As to the argument that the disease remained unrecognised because the cases presented themselves chiefly to surgeons, he would reply by asking who our teachers were. There was John Hunter, who had studied cases of joint disease by the hundred in workhouses and infirmaries; George Langstaff, a poor-law medical officer; John Howship; Cruveilhier; and Mr. Stanley, who collected every species of disease of bone. When we remember that for so long a period as sixty or eighty years specimens of joint and bone disease were assiduously collected by these observers, we cannot but believe that Charcot's disease, if it had a separate existence, must certainly have been detected. And the fact remains that there did not exist in any museum, until recent times, a single specimen of the disease. This kind of evidence was sufficient to prove that the disease did not exist to anything like the extent which it is now found. In general terms he would say that Charcot's disease, if not an actually new malady, was, at all events, a new compound of disease. That the arthritic affection was the result of a neurosis alone he did not believe. He would not say that the disease was neither this or that, but he thought that it was some of these or some of those, a disease which was made up of several constituents, and of an altogether obscure and uncertain nature. So long as it is called after any individual we might conclude that but little was understood of its real nature. The morbus anglicus (or rickets), the morbus gallicus (or syphilis), Pott's disease, and Bright's disease were given as examples to show how diseases owning names derived from more or less accidental circumstances were but imperfectly known. As a practical name for chronic osteo-arthritis he thought rheumatic gout might be used, for no doubt many examples were compounded of these two things—rheumatism and gout. He believed it to be possible that Charcot's disease was a method of rheumatic arthritis altered from its pattern by the intervention of locomotor ataxia; the special character of the nervous disease being quite enough to explain the contrast. In the tabetic arthropathies we had examples of disease with wasting without repair, whereas rheumatic arthritis was a disease of bone with wasting, but with coincident attempts at a reparative process. It could not be said that in Charcot's disease there was no measure whatever of rheumatic arthritis, though the measure might be reduced in some specimens to a minimum, whilst in others the measure would be more obvious. If a careful study were made of all the specimens of rheumatic arthritis and of Charcot's disease it would not be doubted that a certain relation existed between the two. Whilst by drawing our comparison between typical cases, the differences appeared startling enough, yet, if the whole range of joint affections in locomotor ataxy were contrasted with the whole range of joint affections in rheumatic arthritis, it would be seen that as they thus run border and border they became confused on each side. If we considered the possible intervention of three such diseases as rheumatism, gout, and nervous disorder, we might explain a very wide range of characteristics. A very important study was that of the influence of mingling of disease. Syphilis implanted on a rheumatic or arthritic stock would produce in its tertiary stage a wholly different appearance than when implanted on a tubercular soil. The varieties produced by the intermingling and combination of disease would probably explain a great deal which was now but ill understood. A fair extension of that same method of inquiry would lead to the best results. It was but a vain hope to attempt to collect these diseases as examples of one typical form. Instead of seeing in examples of disease a tendency to assume a type—instead, in fact, of pursuing our inquiry in the method of natural history,—he would rather that attempts were made to analyse the cases as minutely as possible, so as to determine what are the several constituents entering into the particular case, and to ascertain in what proportion each constituent enters; in fact, to study specimens of disease after the fashion of organic chemistry rather than after the manner of a system of natural history.

Dr. ORD said he had seen very little of this joint affection, as he had never had a case under his care; but from what he had seen he thought there was a general agreement between rheumatic arthritis and Charcot's disease. He was inclined to agree almost entirely with Sir James Paget. Though he would recognise more than had been recognised, the matter of waste of bone tissue in Charcot's disease, yet he could

Digitized by Google

not concur in the view that no attempts at repair were to be seen in cases of Charcot's disease. He had seen something like eburnation in the articular ends of bones of cases of tabetic arthropathy, and so could not endorse Mr. Barwell's views on this point. In cases which had been classed under the head of chronic rheumatic arthritis we had to do with a mixture of effects. What parts rheumatism and gout might play in the causation it was difficult to say, but there was an absolute necessity to analyse comp'etely all the individual cases which may be included under one common head. He preferred to speak of osteo-arthritis as a more neutral term, implying no pathological theory. That certain kinds of blood-poisoning could produce changes resembling those due to neurotic causes he had but little doubt. Three women who were under his care at the present time illustrated the general lesions of what might be termed chronic osteo-arthritis. The first was that of a young married woman aged thirty-four, who had irregular lesions of the joints of the fingers with wasting and outgrowth; there was ankylosis of the wrists and elbows and of one hip-joint; she had never had gout or rheumatism; the only nervous symptom present was great exaggeration of all the tendon reflexes. In the second case there were well-marked nodosities of the fingers, but no ankylosis anywhere; there was deviation of the digits to the ulnar side, but no nervous affection was to be observed; the patient had had nine attacks of acute rheumatism and cardiac disease was present. In the third case there was enormous thickening of the joints, with looseness of the ligaments, deviation of the hand, and subluxation of some joints, associated with a glossy condition of the skin and wasting of the nails and muscles, together with subcutaneous nodules. He submitted that there were differences enough in these three cases; there could be no question of the necessity of analysing this very obscure and difficult affection of the joints. Whilst there were strong evidences of a neurotic influence of a direct or reflex nature, he could not help thinking that there were many other causes which might give rise to similar changes.

Professor HUMPHRY said that he entirely agreed with the remarks of Sir James Paget; that such rockings and such deformities of articular surfaces could have passed unobserved in past times he thought was an impossibility. A comparison was drawn between the changes in the two diseases under discussion. In the one there was a low inflammatory affection with but a slow change in the articular surfaces, whilst in the other there were rapid decaying, wasting, or removal of bone. These features were most marked in a specimen which he exhibited to the Society. The tibia was greatly wasted and the decay of the bone beneath the articular surface had allowed the cartilage to become applied against the articular surface of the femur. There was not an absence of reparative process, and he compared the changes in Charcot's disease to those met with in intracapular fracture of the neck of the femur, where there were considerable outgrowths at the base of the trochanter with wasting of the head and neck. The quick repair of bones in old persons was in striking contrast with the atrophic change of the whole osseous system. It was astonishing how bone repair was so rapidly called into existence in old people.

Mr. JOHNATHAN HUTCHINSON said that he had been to see Charcot's cases when the disease was first proclaimed. In his lectures delivered at the College of Surgeons on the Relation of the Nervous System to Lesions of Nutrition he exhibited the first series of cases in this country, though Dr. Buzzard was the first to mention the disease here.[1] At first he was inclined to agree with Charcot that the disease was *sui generis*. But later on he doubted whether there was an active interference on the part of the nervous system in Charcot's disease and chronic rheumatic arthritis. In the lectures referred to he had made a special point of the changes in old age as being like those met with in the joint affection of locomotor ataxy and the term "morbus coxæ senilis" was illustrative in this relationship. He considered that the arthropathy of locomotor ataxy resembled a sort of tumultuous old age, a premature senility of the nervous system accompanied by a remarkable loss of sensation. This anæsthetic state was common to senility and locomotor ataxy. The loss of sensation in the bladder might lead to urinary retention, and he believed that perforating ulcer of the foot was induced by external causes acting in conjunction with the loss of sensation, and a conclusive proof of this ulcer being the result of pressure was afforded by the results of treatment. Sir James Paget had spoken of the nervous system as acting passively in permitting disease and not actively in causing lesions. And this represented Mr. Hutchinson's view in regard to tabetic arthropathy. He believed that there was no abrupt line of demarcation in the pathological appearances of Charcot's disease and chronic rheumatic arthritis, but the differences were very great, indeed, when typical forms were contrasted; but where the forms were not typical our ability to discriminate between the two might be very much at fault. The influence which the nervous system exercised in the production of the arthritic changes in locomotor ataxy was a purely passive one; the patient, owing to his long endurance as the result of the loss of susceptibility to pain, allowed destructive processes to go on. In the same way he would explain the other diseases which were credited to neurotic changes. His views on trophic lesions remained very much where they were when he lectured on the subject at the College of Surgeons.

Sir ANDREW CLARK asked Sir James Paget to explain more fully his views on the relation of the nervous disease to the tabetic arthropathy.

Sir JAMES PAGET said he would not be disposed to say that the joint changes are dependent merely on the nervous system, but he did not think that the nervous influence was simply a permissive and passive one. It would be difficult to say what morbid change actually determined the disease, though he believed that the nervous system had a definite power of producing disease in this part or that part. In such an example as herpes zoster, where the neuralgia continued after the eruption had disappeared, he believed that a nervous disturbance was the exciting cause, but the special character of the eruption was not determined by any condition of the nervous system. An error of nervous force determined the lesion, but why the eruption should be vesicular and not a scaly or ulcerative one was probably dependent on causes outside the nervous system. In symmetrical gangrene the nervous system played a part, but in none of the cases was it a simple disease. The affection was not solely determined by error of nervous force, but the method and manner of the external appearance of the disease was dependent on many other causes, such as gout, rheumatism, syphilis; and so individuals were prone to a disease in this or that method whilst the determining cause lay in the nervous system.

Mr. WHITAKER HULKE said that he felt unable to agree with those who looked on Charcot's disease as a separate malady. In malum senile or arthritis sicca, or by whatever name it be called, the joint disease in its anatomical appearances did not present any essential difference from a tabetic arthropathy. In the same individual he demonstrated excessive wasting of the humerus, with a knee-joint having but little wasting of the bones, but with numerous stalactitic outgrowths, whilst there was no neck to the femur, whose upper end showed an eburnated surface. Here there was a mixture of changes, and it would be difficult to say whether the bone changes were most like those of Charcot's disease or like those of chronic rheumatic arthritis. Then Mr. Barwell had said that the lesser joints were not affected in Charcot's disease, but this was not correct, for Mr. Hulke placed before the Society a foot having extensive wasting and disease of all the joints, and this specimen was sent by Charcot as a specimen of tabetic arthropathy. Then, in regard to the clinical course, he narrated the case of a French woman, who was an actress and dancer, and who suffered from unequivocal signs of locomotor ataxy, who presented enlargements of the joints of both lower limbs. One day a sudden swelling, attended with excruciating pain, appeared in one of the knee-joints, which swelling fluctuated; there were heat and redness, with tenderness; in fact, all the signs of an acute synovitis. This example proved that the joint changes were not always perfectly sluggish in their clinical manifestations. Many examples of tabes dorsalis occurred in which there were no articular affections; other instances of joint affection were met with in which there were no symptoms of tabes dorsalis, and again we had instances in which the two were concurrent. It was difficult to speak with certainty on

[1] A clinical lecture by Dr. Buzzard on "A Case of Progressive Locomotor Ataxy with Anomalous Joint Affection," with an illustration, appeared in THE LANCET of August 22nd, 1874, and another by the same author upon a second example of joint affection in locomotor ataxy on January 18th, 1879. The first case of the kind reported in England was by Dr. Clifford Allbutt in the St. George's Hospital Reports, 1868.—ED. L.

Digitized by Google

the nature of the association of tabes dorsalis and joint affection. Syphilis might play a part in the causation.

Specimens of Charcot's Disease were exhibited by Messrs. Morrant Baker, Bowlby, Makins, Morris, Tyson, Porter, and Godlee, and by Drs. Lunn, Lees, Coupland, and Hadden, also by Mr. Francis for Professor Humphry.

Dr. Hale White showed a living specimen of an unusual case of Psoriasis.

MEDICAL SOCIETY OF LONDON.

Gastrostomy.—Cervical Cysts.

AN ordinary meeting of this Society was held on Monday last, Mr. Arthur E. Durham, President, in the chair.

Mr. BOYCE BARROW read a paper on a case of Gastrostomy in which he wished to draw special attention to the method of operation which he had employed. The patient began to suffer from dysphagia and pain last Christmas. He was treated till July 10th, 1884, as an out-patient. Pain was chiefly experienced at the sternal notch. Dysphagia and vomiting were marked symptoms, blood being sometimes ejected. An incision was made parallel with the lower costal margin and an inch and a half below the xiphoid cartilage, about a finger's breadth from the costal margin. After the muscles had been divided and the peritoneum opened the colon presented, and some trouble was experienced in finding the collapsed stomach, which was now secured to the edges of the wound by means of pins. The operation was performed antiseptically, iodoform and a dry dressing being used. Vomiting and collapse for a few days were followed by complete recovery. Rectal feeding had been employed, and the stomach was not opened till the tenth day after the operation, though the pins were not removed, yet no irritation ensued; moreover, the presence of the pins ensured complete and firm union. A tracheotomy tube of indiarubber material was introduced into the stomach for the purpose of feeding. The patient gained a stone in weight, and was growing more cheerful. Death occurred four months after the operation. Symptoms of blood-poisoning had supervened only ten days before death; abscesses were found in the cerebellum, cerebrum, and kidneys; also many petechiæ were seen under the serous membranes of the heart and lungs; the spleen was gangrenous at one part; the œsophagus was much ulcerated; and the malignant growth had involved the pericardium and left auricle of the heart. The advantages of this operation were its simplicity and the great amount of surface contact of the peritoneal surfaces.—Mr. DUNN had made the autopsy. The œsophagus was healthy as far as the sixth dorsal vertebra, where the œsophagus was thickened and infiltrated with cancerous material, much sloughy material depending into the cavity. In the middle lobe of the left lung there was an abscess, the size of a walnut, containing foul-smelling pus, which had a blood-stained appearance; there were abundant ecchymoses in the parietal and visceral layers of the peritoneum; a portion of the spleen was gangrenous; and the left auricle of the heart was infiltrated.—Mr. FRANCIS MASON asked for the age of the patient; it was important to consider when to open the stomach; and though Mr. Barrow had said it might be done on the second day, yet he doubted the propriety of opening so early. Two years ago he showed a specimen at this Society, in which the man had died on the third day, but the adhesions were by no means firm.—Mr. BLACK referred to the operation as performed by Mr. Macnamara, in which sutures were used.—Mr. PEARCE GOULD had performed gastrostomy five times, and in one case the patient lived for one month; the disease was situate at the back part of the trachea, and had ulcerated into that tube, causing death. He had had no difficulty in finding the stomach. The operation as performed by Mr. Barrow possessed the great advantage of fixing the stomach with the pins, and so enabled one to open the stomach earlier than if mere sutures were employed. Patients may be lost by their having to wait six or seven days before the stomach could be opened. We could not argue from cases of hernia to these cases because of the feeble state of the nutrition of patients requiring gastrostomy.—Mr. B. JESSETT would like to know whether all the coats of the stomach were transfixed or not.—Mr. B. BARROW said the man's age was fifty-two. The pressure of the harelip pins was beneficial in securing contact. Indiarubber protected the patient from the sharp points of the pins. The pyæmia was probably due to embolism of the splenic artery, the embolon being derived from the site of the malignant disease.

Mr. JOHN H. MORGAN read a paper on Cysts of the Neck. He arranged them into cysts due to change of normal structures and those due to developmental errors. Of the first category, there were bursal tumours and hydrocele of the neck. Cystic hygroma and congenital sebaceous cysts belonged to the second class. The situations in which they were found where in front of the pomum Adami and between the posterior surface of the hyoid bone and the upper surface of the thyroid cartilage. They might appear as rounded smooth collections of fluid moving with the larynx. Hydrocele of the neck has been described by Cæsar Hawkins and others. The difficulty was to distinguish them from solid tumours. The employment of a fine trocar might be useful in diagnosis, as in one case in which a dark fluid was evacuated. In contrast with this case was that of a woman, aged forty-seven, in whom the swelling turned out to be malignant. The size of the cyst may vary from that of a walnut to that of a cavity holding a pint of fluid; their effects depended on their size and situation, and they were single as a rule. Congenital cystic hygroma is most frequent in the neck, and here the growth lies beneath the fascia and spreads in the intermuscular spaces; the growth is always polycystic. These cysts assume every variety of colour and consistence. The walls may contain solid masses composed of connective tissue. Sir James Paget had suggested, in the Medical and Chirurgical Transactions for 1878, that there was a probability that some congenital and infantile cysts may be derived from branchial canals closed at both ends and distended with fluid. Mr. Morgan did not think these views satisfactory, chiefly on account of the situation of the growths and of the nature of their contents. Cases illustrating the method of treatment by puncture were narrated. Mr. T. Smith had recommended the use of Morton's fluid and setons of catgut. The readiness with which these structures became inflamed and their deep connexion were arguments against this method of treatment. Sebaceous cysts were doubtless the remnants of some errant portion of epiblast, and are generally formed in connexion with the branchial arches. Other relics of these branchial clefts and arches were supernumerary auricles and branchial fistulæ. Hydatids may also be found in the neck.

Mr. DURHAM exhibited a boy, aged fourteen, who was under his care at Guy's Hospital. He presented a large fluctuating tumour on the left side, extending from the lobe of the ear to within two fingers' breadth of the clavicle. The swelling was first noticed about four years since. Two years ago it was lanced, and a quantity of blood and serum came away; this operation was twice repeated, but the tumour had again filled after the third operation. He had found that these cysts had very deep connexions.—Mr. W. ROSE observed that it was exceedingly difficult to arrive at a diagnosis as to the nature and relations of the cyst. He referred to the case of a gentleman, aged fifty-five, who had a cervical cyst containing clear fluid; the swelling rapidly filled after being tapped, and a week later the fluid was found to be blood-stained, and a firm nævus could be felt; death ensued from extension of the malignant disease.—Mr. PEARCE GOULD inquired whether Mr. Morgan had ever met with a "blood cyst" so-called, from which it was said that exceedingly free venous bleeding occurred. He had been surprised to hear that Mr. Morgan had met with blood so often in hydrocele of the neck. In one case which Mr. Marshall had dissected out entire, Mr. Gould had made a nitrate of silver preparation of the wall of the cyst, and obtained clear evidence that it was connected with the lymphatic system.—Mr. MORGAN agreed with Mr. Rose in his observation with regard to the difficulty of arriving at a diagnosis, even after tapping, owing to the variable quality of the fluid. He suggested that the "blood cysts" referred to by Mr. Gould were either vascular sarcomata or cysts in direct connexion with one of the large veins.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY

AT a meeting of this Society on November 6th,

Dr. PORTER introduced a case of Embolism of the Central Artery of the Retina occurring in a patient suffering from mitral regurgitation; it was not associated with any other embolic symptoms. The sudden occurrence of the symptoms and the ophthalmoscopic appearances were very charac-

Digitized by Google

teristic.—Mr. S. SNELL, remarking on this case, referred to the cases recorded by Eales, Wood, and White, in which the blood current rapidly became re-established, and also to a case in his own practice in which it would appear that at the outset very temporarily the whole artery was obliterated, but that the plug had later passed into the lower retinal branch. Three years later vision was still absolutely lost in the portion of the field, but in the other V=$\frac{1}{3}$.

Mr. PYE-SMITH showed several hundred "Melon Seed" Bodies which he had recently removed from a Ganglion in the Flexor Aspect of a Man's Wrist. The operation was done with Listerian precautions, and the wound soon healed.

Mr. PYE-SMITH also exhibited a Portion of Ileum with Perforation and three Grape Stones from a case of Strangulated Right Femoral Hernia in a woman aged forty-two. Herniotomy was performed directly after admission to the public hospital on the third day of strangulation. On opening the sac there was a fæcal smell, but as no perforation of the knuckle of intestine could be detected it was returned just within the peritoneal cavity, and a drainage-tube placed in the wound. On the fifth day after the operation fæces began to escape by the wound, and three weeks later the patient had fresh symptoms of obstruction, and a tumour formed between the artificial anus and the liver. In three days pus and fæces in large quantity made their way through the fæcal fistula, and the abscess tumour subsided. The woman lived two months after the operation, and died exhausted. On post-mortem examination the perforated bowel was found lying near the middle line, and in connexion with it there was a fæcal abscess cavity extending from the wound upwards in front of the cæcum and ascending colon to the liver; the intestines around were closely connected by adhesions blocking off the general peritoneal cavity. Just under the liver, in the fæcal cavity, were three grape stones. It was thought that these stones had led to the second attack of obstruction by blocking up the small opening in the skin, until they had gravitated backwards in the pus that formed.

Dr. SINCLAIR WHITE exhibited a specimen of Congenital Sarcoma of Hand in the First Interosseous Space in a boy aged eighteen months, who was a patient in the public hospital last July, under the care of Dr. Keeling. The tumour, which was as large as a walnut, was removed on August 6th, and had to be scraped away from the first and second metacarpal bones, to both of which it was adherent. The wound healed and all went well until the middle of September, when the tumour reappeared and grew with such rapidity that in a fortnight it equalled the size of the hand. It was very vascular and bled freely. On Oct. 8th amputation above the wrist was performed. The tumour was a succulent round-celled sarcoma, and sections under the microscope were shown. At present there was no recurrence of the disease.

Dr. DYSON exhibited a specimen from a case of Cancer of the Colon. The patient had been ill over a year. At first the symptoms were those of dyspepsia, with pain in the right flank. In February, 1884, he was acutely ill with pyrexia (103° F.), slight congestion at the base of the lungs, diarrhœa, and a tumour in the right flank. He passed some pus and blood per anum, and the symptoms and physical signs diminished. The temperature fell to normal. In June he was admitted into the public hospital, and was very anæmic, feeble, and febrile. On the day of admission, after a rigor, the temperature rose to 105°. The tumour since February had much increased in size, and reached from the liver above, with which it was continuous, to the iliac crest; its lower part was sub-tympanitic, and the upper absolutely dull; it was exquisitely tender. It did not distinctly follow the movements of the liver in respiration. There were night-sweats, with high evening and low morning temperatures. Urine, sp. gr. 1018; no albumen. The tumour was twice explored with a hypodermic syringe; on each occasion only a little pus with blood-corpuscles and débris came away. Quinine was given for the pyrexia, opiates for the pain, and astringents for the diarrhœa, which supervened towards the end. The right leg, and then both legs, became œdematous. The blood was examined, but no leukæmia was present. He died on Aug. 3rd, 1884. At the post-mortem a broken down cancerous mass surrounding the upper part of the ascending colon was found; it extended to the neighbouring part of the liver. In the centre of the growth was a cavity containing purulent matter and débris. All the surrounding tissues were infiltrated, but there were no secondary deposits. Dr. Dyson remarked on the variety of malignant disease of this portion of the bowel, on the difficulty of diagnosis, the rigors being suggestive of pericolitic or perinephritic abscess. The physical signs found during life were very clearly explained by the post-mortem conditions.—Mr. W. A. GARRARD, Dr. KEELING, and Dr. HUNT made observations on the case.

Mr. PYE-SMITH related notes of several cases occurring in general practice. The first was a case of widely diffused Lupus Erythematosus in a man aged sixty-seven, who had been suffering from it for three years. The parts affected were the face, head, neck, chest, and back. It was accompanied with great itching. At present no improvement had been effected by treatment. The patient was introduced. The second case was that of a young married lady, who, after a normal first labour, had on many occasions during the first three weeks exhibited a temperature between 104° and 106·2°. The rise was usually in the morning, and often after lack of sleep. There had been no other signs of serious illness, local or general, and the patient was convalescent and sitting up when the highest temperature was recorded. She was of a somewhat nervous temperament. The third case was one of continuous moderate high elevation of temperature during a period of more than six months, accompanied by various symptoms of disease, and ending in convalescence. The patient was an excitable young lady, aged seventeen. She gave a history of having recently been under treatment for inflammatory consolidation of the base of the left lung. The present symptoms were mostly hyperæsthesia, especially of the abdomen, dyspepsia, irregularity of the bowels, painful micturition, emaciation, flying pains in the limbs, and lowness of spirits. During the illness a small chronic abscess formed on the inner aspect of the right elbow, which healed after antiseptic incision. She also had a small abscess in the lobe of the left ear. The temperature ranged usually between 100° and 102°, the extremes being 99·2° and 103·2°. There was never any cough, and the patient always slept well. Physical examination always gave negative results. The temperature had now fallen to normal, and the patient had regained flesh and pretty well lost her pains, &c. The case was regarded as nervous (quasi-hysterical); but for many weeks gave great anxiety, the chief fear being tuberculosis in some form. The fourth case was one of general Anasarca occurring without Albuminuria in a married lady aged twenty-eight. The anasarca was well-marked in the ankles, legs, thighs, and slightly in the lower eyelids, the abdomen was also enlarged, but there was no fluid in the peritoneal cavity. The first time the urine was examined (about third day of œdema) it gave a slight cloud with tincture of galls, but on no subsequent occasion. It was tested daily and never gave any cloud with heat, nitric or picric acid. In ten days the patient was well. There was no history of previous scarlatina. Menstruation was regular. Mr. Pye-Smith referred to remarks on such cases by Dr. Dyce Duckworth, vol. xix., St. Bartholomew's Hospital Reports.

Reviews and Notices of Books.

A Handbook of the Diseases of the Eye and their Treatment. By HENRY R. SWANZY, A.M., M.B., Surgeon to the National Eye and Ear Hospital, Dublin. Pp. 437. London: H. K. Lewis. 1884.

WE have great pleasure in recommending this work to all students and practitioners who desire to acquire such a knowledge of the defects and diseases of the eye as will render them competent to recognise and undertake the treatment of any ordinary case which may present itself in practice. The author rightly states that a handbook can only be regarded as an aid, and must not for a moment take the place of clinical study. Just as it is impossible for the student to learn anatomy from plates, however well they may be drawn, so no picture of a disease sketched by the eye and hand of another can supply the place of actual observation.

The chapters to which the ophthalmic surgeon naturally turns in looking through the pages of a new work are those devoted to sympathetic ophthalmia, glaucoma, and cataract.

Digitized by Google

Each of these affections presents difficulties of its own which sorely tax the judgment, and all are glad to learn the rules by which another is guided, and the practice he adopts. Mr. Swanzy distinguishes between sympathetic irritation and sympathetic ophthalmitis. The former he regards as a reflex neurosis, whilst the latter appears to be an extension of inflammation from one eye to the other, through the optic nerves and chiasma, and this seems to be the general opinion at present. The principles by which he is guided in recommending removal of an eye after injury, lest sympathetic ophthalmia should follow, appear to us sound and unexceptionable. They are briefly these. He removes any eye that is completely disorganised by injury, not only if seen immediately after the accident, but even when irido-cyclitis has become established, more especially when vision is lost. He enucleates any eye with irido-cyclitis that there is reason to believe has an irremovable foreign body in it. He removes atrophied and tender eyes. He enucleates the exciting eye, even when the other eye has become affected, believing that such removal tends to allay the inflammation in the sympathising eye; and, lastly, he enucleates even where there is only sympathetic irritation, if the sight of the exciting eye is very defective. He further lays down the rule that an injured eye should not be removed if there be no foreign body in it, and the sight is fairly good; and he would not enucleate the exciting eye if there appeared to be good reason for thinking that its vision might be superior to the other. These rules are dictated by the results of large experience, and of careful scrutiny of recorded cases, and are worthy of consideration in all doubtful and difficult cases.

In reference to Cataract Extraction, the author appears to prefer De Wecker's three millimetre flap, though the illustration and the description do not quite agree, owing to De Wecker making the downward section, whilst the drawing represents an upward one. He performs a small iridectomy as a second stage of the operation, this step being facilitated by the previous instillation of eserine.

In the treatment of Glaucoma Mr. Swanzy is a firm supporter of the method introduced by his old master, v. Graefe—viz., the operation of iridectomy. This proceeding has, he says, until lately, held an undisputed position as the sovereign remedy for glaucoma, and even yet has, he thinks, suffered but little from the competition of the proceeding termed sclerotomy. Sclerotomy he can only find in his heart to say has proved useful as a remedial measure in glaucoma, and observes that it has hitherto been employed more in chronic simple glaucoma, in which iridectomy is less satisfactory than in acute or subacute glaucoma. It should not be undertaken in cases in which eserine will not produce myosis. We think Mr. Swanzy rather underestimates the value of eserine when he says that the great use of its application will be found in cases of acute glaucoma where it is desirable to postpone operation for a few days, and in cases of chronic simple glaucoma where it may be desired to avoid, if possible, any operative interference. He admits, however, that a small percentage of cases of acute glaucoma may be radically cured by a few instillations of a solution of the drug.

The earlier chapters on Elementary Optics, Abnormal Refraction and Accommodation, and the Ophthalmoscope, are very clearly yet concisely given; and indeed throughout the book no pains have been spared to make the descriptions of the various diseases as brief as is compatible with perspicuity, and the type and illustrations are alike excellent. There is a very good chapter on the Physiology of the Iris, and a set of wools constituting Holmgren's tests for colour-blindness is pasted into the cover of the book. The work, as a whole, is most creditable to Mr. Swanzy, and in all respects represents well the present state of ophthalmic science.

Humphry Sandwith. A Memoir. Compiled from Autobiographical Notes by his Nephew, THOMAS HUMPHRY WARD. Pp. 261. London: Cassell and Co. 1884.

THE life of Dr. Humphry Sandwith is a most interesting book. It has been condensed by his nephew from a very full autobiography, drawn up during the later years of his life from the diaries which he had kept, and from much interesting correspondence. In the form in which it is presented to us it gives a history of his early struggles, of his first professional start in Constantinople, his wanderings with Layard through Armenia and Kurdistan, his work in Mesopotamia, his return to Constantinople, his appointment as surgeon on the staff of General Beatson when he raised the Corps of Bashi-Bazouks, his transfer to that of General—afterwards Sir Fenwick—Williams, and his services at the siege of Kars; his return to London, and appointment to the special embassy which was sent from this country to attend the coronation of the Emperor Alexander II. at Moscow, his subsequent brief career as Colonial Secretary to the Mauritius, and the services which he rendered, in connexion with the National Aid Society, to the wounded in the Franco-German, Servian, and Russo-Turkish wars. We cannot enter at any length into the details of his varied career, but this is the less necessary as we can recommend the work as being very readable, and full of interesting anecdotes. There is, however, one point which we think deserves special notice—the successful manner in which, under circumstances of great difficulty, he carried out the medical service of the army in Kars. In February, 1855, he was appointed by General Williams Inspector-General of Hospitals, with a staff of about fifty persons, physicians, surgeons, and apothecaries, "the two latter classes being entirely ignorant." The medical stores, which he found at Kars were "a marvel and a phenomenon," consisting chiefly of "cosmetics, aromatic vinegar, *eau de luce*, scents and other dainties, and medicines *de luxe*, besides sundry instruments destined for the infirmities of ladies in an interesting condition; but the medicines really necessary for the use of an army in the field were scarcely to be found, and the few that did exist were of the most worthless description." Setting to work zealously, backed up by his General, whom he describes as "the terror of Pashas great and small," and utilising to the utmost the resources of the country, Dr. Sandwith got his department into good working order before the siege of Kars began, on June 9th. From that date till Nov. 27th, when the town surrendered, his hands fall of work, not merely from the consequences of the ordinary operations of a siege, but from an outbreak of cholera, and from the effects of cold and starvation upon the troops. It speaks well for the arrangements he made that, under such deplorable circumstances, "during the whole siege of Kars we never had an epidemic of typhus, nor did that enemy of surgery—hospital gangrene—ever appear." It is gratifying to find that two days after the surrender of Kars General Mouravieff gave Dr. Sandwith his unconditional liberty, "in special recognition of the services which he had rendered to the Russian wounded who had fallen into Turkish hands after the battle of September 29th."

Mr. Ward has discharged in a very satisfactory manner the difficult task of collating this memoir. He has brought out the leading occurrences of an eventful life in a pleasing manner, without endeavouring to make the subject of it a faultless hero. Sandwith was fearless, honest, and high-minded, sometimes too impetuous and self-reliant. The history of his life leaves with us a regret that his early education was so desultory. Had he enjoyed the advantages of a better training, we feel that distinguished as he was, he would have been still more so, and probably would [illegible] the present time his account of the Turks [illegible] thirty years ago—and as we fear they still [illegible] he

Digitized by Google

found pleasant reading. The memoir has given us much pleasure, and we can recommend it as an interesting record of a distinguished member of our profession, and the perusal of it as an agreeable relaxation from more serious work.

Analytical Records.

[WE think it right to direct attention to the system we adopt in the conduct of this department. Of the numerous articles of food and medicine submitted to us we select such as we think important to the medical profession and the public. Samples of these are bought by us in the ordinary way, and the results of our examinations reported.]

AERATED WATERS.

(CLAYTON BROS., RUTLAND-STREET, PIMLICO.)

We have analysed several of the aerated beverages made by Messrs. Clayton Bros., and also the water used in their manufacture. The water is the ordinary London supply, purified by precipitation as well as by filtration. The precipitation is an important additional security for the purity of the water, for it is well known that a precipitate in falling carries down with it suspended organic matter, the most dangerous contamination of drinking-water. With regard to the soda-water, potash-water, and lithia-water, all that need be said is that each was proved on analysis to contain, approximately, the proper quantity of the salt indicated by its name. The Brighton seltzer-water contained the carbonates of lime, magnesia, and soda, chloride of sodium, &c., and the sample analysed was practically identical in composition with natural seltzer-water from the spring. Of course it is a mild saline alterative. The evaporated residue was hardly coloured by ignition, showing the absence of organic matter. Messrs. Clayton's ginger ale is an excellent substitute for alcoholic beverages, and will be useful to many who from choice or necessity abstain from beer, for it is not too sweet and is free from the rough taste of crude ginger, which shows that the resin of the root has been successfully removed.

PROFESSOR TUSON'S DISINFECTANTS, LIQUID AND SOLID.

(MANUFACTURERS: A. BOAKE & CO., STRATFORD. AGENTS: BAISS BROS. & CO., JEWRY-STREET, LONDON.)

Of these disinfectants, which are distinct novelties in sanitation, the liquid appears to be essentially a solution of chloride of zinc saturated with sulphurous acid, and the solid a mixture of the sulphates of zinc and alumina and the sulphite of lime. Every chemist knows that sulphate of alumina and sulphite of lime decompose one another in the presence of water, with formation of sulphate of lime, alumina, and free sulphurous acid. Sulphurous acid is the oldest and best known, and certainly one of the most trustworthy of disinfectants, and the soluble salts of zinc are also of great and universally admitted value. Professor Tuson's union of the two combines, very happily, the advantages of both. Both, as antiseptics, are deadly to organisms of all kinds, and they possess the power, which carbolic acid is deficient in, of destroying the noxious products of putrefaction and the offensive odours emitted from animal excreta. When they are used jointly, as in these preparations, foul odours vanish as if by magic, and no disagreeable chemical smell remains to take their place. We have submitted these disinfectants to the test, not only of analysis, but of practical use. The solid is applied by a dredger, and when a little is sprinkled over a night-stool all smell is gone in a minute. The liquid, like other liquid disinfectants, must be diluted according to the directions on the label. When suitably diluted it has but little smell and no injurious action on textile fabrics. This last fact is noteworthy. The first idea of the chemist would be that the sulphurous acid, absorbing oxygen from the air, would form sulphuric acid, which would damage articles of dress and the like. But we can testify that no such damage takes place, possibly on account of the great dilution of the solution. We have seen woollen and cotton goods soaked repeatedly for hours in a solution strong enough to destroy infection, which yet, after washing, were entirely uninjured. It must, moreover, be remembered that sulphurous acid is commonly used as a bleaching agent.

PURE CONDENSED COW'S MILK (EDELWEISS).

(THE SWISS MILK COMPANY, 84, BASINGHALL-STREET.)

This preparation, which keeps well in the bottles in which it is sold, is, we find, genuine condensed milk, unsweetened and untreated with antiseptics. When mixed with twice its bulk of water it yields a milk fit for ordinary household purposes, not very rich, but rich enough to pass the tests of the public analyst. With an equal bulk of water a really rich milk is obtained, in which we found over 16 per cent. of total solids. In both cases the flavour is excellent. We consider the article useful and trustworthy.

CONDENSED CREAM EMULSION (CREMOR HORDEATUS LOEFLUNDI).

(LOEFLUND & CO., 148½, FENCHURCH-STREET.)

Messrs. Loeflund's well-known Hordeum Malt Extract is here emulsified with fresh cream. The result is a very palatable and easily digestible food, which may be compared with the cod-liver oil and malt extract which has come so much into favour of late. The chief constituents of malt extract are, of course, maltose and dextrin, and these soluble and easily digestible compounds seem to render the assimilation of oils and fats more easy. The diastasic, or starch-converting, power of this particular preparation is, however, low.

CEYLON TEA: PURE CEYLON TEA GROWN BY THE CEYLON COFFEE COMPANY.

(H. HEWETSON & CO., 59, MARK-LANE.)

Genuine young tea, of the kind which attained such popularity in the Ceylon stall at the late Health Exhibition. The leaf is unfaced, as is shown by the fact that we found in it only 5·24 per cent. of ash, which agrees with that found in the best Assam. China has a formidable rival in Ceylon.

DISEASED MEAT.

To the Editor of THE LANCET.

SIR,—With regard to your article on "Diseased Meat" in this week's LANCET, in reference to a case brought before the Tiverton magistrates, in which the question was raised as to the fitness for food of the carcass of a cow which had suffered from "milk fever," will you allow me to state that this term is wrongfully used to designate two very different diseases. These are "puerperal eclampsia" or, better, "puerperal apoplexy," and "puerperal" or "septic fever." Many mistakes have occurred through this confusion, and especially that with regard to the utilisation of the flesh of cows which have suffered from these diseases; and in my work on Veterinary Obstetrics I have laid particular stress on their distinctive features. In puerperal apoplexy, which was, I presume, from the symptoms enumerated, the malady from which the cow in question suffered, there is no "fever;" the attack is sudden, with all the symptoms of apoplexy; a fatal and prompt termination is, in the majority of cases, inevitable, notwithstanding the most active remedial measures. Provided the animal has not been drugged with injurious or unpleasant-smelling medicines, the flesh is innocuous, and therefore need not be condemned as unfit for consumption. In puerperal fever, on the contrary, there is a high degree of fever and the flesh is dangerous, inasmuch as the animal was suffering from septicæmia. The use of such flesh should undoubtedly be prohibited, though, I fear, it sometimes reaches the butcher's stall. The term "milk fever," a condition which is not often seen in animals, is not applicable to any of these morbid states. There should not be much difficulty in deciding whether an animal has died from puerperal apoplexy or puerperal fever on examination of its carcass. The case upon which you have commented was, in all likelihood, one of the first-named disease, and the decision arrived at by the magistrates was justifiable. The flesh of a cow which, after the birth of a calf, had been killed because of this apoplectic state is not unwholesome.—Yours truly,

GEORGE FLEMING, LL.D.,

Nov. 29th, 1884. Principal Veterinary Surgeon to the Army.

THE LANCET.

LONDON: SATURDAY, DECEMBER 6, 1884.

IN our last number we referred to the impossibility of obtaining from the University of London any of the reforms in medical education which have been suggested by medical teachers and graduates in recent years. The recommendation of holding a Preliminary Scientific Examination twice a year has been ignored, even when urged more than once by the Annual Committee and the graduates in Convocation, and supported by the deans and teachers of the principal medical schools; the letter of Dr. BRISTOWE, a distinguished graduate and a former examiner in medicine, has been treated with scant courtesy; and the suggestion that "boards of studies" might bring the Senate into closer relation with the teaching bodies has been almost contemptuously bowed out of court. Is it, then, any wonder that medical teachers have felt aggrieved, and that they despair of making any impression on a University whose authorities pay no attention to any criticisms, however friendly, on their line of action, and who give no heed to any suggestions of reform? The Senate, so far as medical training and qualifications are concerned, is possessed with only the one idea, that its mission is to "improve medical education," and firmly believes that the only method of accomplishing this is to be always raising its standard—that is, to leave out of consideration the average well-informed and hard-working student, and concentrate its energies on harassing the ambitious and able by making its examinations as difficult and its degrees as unattainable as an irresponsible board can make them. When we find that after forty-six years of existence only twenty-two gradnates per annum have on an average obtained the M.B. degree, we must confess that it seems to us to have succeeded to the utmost in its unwise procedure. Even in the last eight years an average of thirty-eight represents the total number of medical graduates from all the metropolitan and provincial schools, including even some who have been taught at the other universities. In 1884 there were eighty-nine more candidates for the Preliminary Scientific Examination than in 1877, but only thirty-one more passed. Almost every student who enters for the Preliminary Scientific Examination should be able by honest work to obtain a degree, for his general intelligence and culture have been already tested at the matriculation examination. But the University of London does not concern itself with a medical student of even this amount of industry and capacity.

What probability is there of altering such an unsatisfactory condition, and of persuading the University authorities to depart from their present absurd position? We fear none. The reasons for such a desponding view are to be found in the anomalous constitution of the Senate, and in the unfortunate certainty that, while it will not move towards any reform from within, by giving some control over its examinations to the teachers or their representatives, it is impossible to compel it to do so from without. The official bodies in the University are the graduates constituting the Convocation, with an Annual Committee, and the Senate, composed of thirty-six Fellows, with a Chancellor and a Vice-Chancellor. The Annual Committee can only advise Convocation upon any matter affecting the interests of the University, and even then only if the question has not been referred by Convocation to a special committee. The functions of its thirty-two elected members—*ex officio* members are rarely present—are therefore limited to finding matters for Convocation to discuss, and to making reports on such subjects either by their own free will or at the request of the graduates in Convocation. The powers of the members in Convocation are thus defined by the Charter of 1863:—"The power of discussing any matter whatsoever relating to the University, and of declaring the opinion of Convocation in any such matter; the power of deciding as to the recognition, upon such terms as the Senate shall propose, of any degree to be hereafter conferred under their own Charter, other than the said degrees in Arts, Laws, Medicine, and Science, as a qualification for admission to Convocation; the power of accepting a new or supplemental Charter, or the surrender of their own Charter or of any new Charter or supplemental Charter (with the consent of the Senate); the power of deciding on the mode of conducting and registering the proceedings of Convocation; the power of electing a chairman and of appointing and removing a clerk and of prescribing his duties; and, lastly, the power of nominating three persons whenever it is the turn of Convocation to elect a Fellow on the Senate, from whom the Crown shall select one. Except as expressly hereby provided, Convocation shall not be entitled to interfere in, or have any control over, the affairs of the University." In addition, the graduates who are entitled to vote in Convocation elect a Parliamentary representative for the University. The powers of the graduates are therefore limited to discussing the affairs of the University and to determining their own mode of so discussing them, to electing their own chairman and clerk, to voting for a Member of Parliament, to joining in the acceptance or refusal of a new or supplemental Charter, and to occasionally nominating a member to represent them on the Senate. Could more careful limitations of their powers have possibly been devised? If it were not for the last two provisions, meetings of Convocation would be always mere futile assemblies for exhibiting the debating powers of those present, as is usually the case, for its members have only been called on to act at intervals of years. How can active, busy men, be expected to attend such meetings regularly? And why should they? Moreover, by the mode of election of Fellows on the Senate the influence of the graduates on this body is reduced to a minimum. Every member of the Senate is appointed for life. Only nine out of thirty-six Fellows can be appointed by Convocation—that is to say, one member in every four is elected by his fellow-graduates; and when a vacancy to be filled by Convocation occurs, the list must even then contain three names for the Crown to select from, whilst three members in every four are nominated directly by the Crown without the intervention of Convocation. But it is a tacit arrangement that the Faculties of Arts and Law select alternately with those of Science and Medicine, so that only one

Digitized by Google

in every eight really represents these two faculties. Again, as the Science graduates are as jealous of their privileges as are those with medical degrees, it follows that the choice of one member of the Senate out of every sixteen, or two and a quarter of the whole body, is all the direct representation that the medical graduates can expect to possess under the Charter. Only *one* medical graduate has, in fact, been elected within the past twenty years. It is therefore not without justification that we have called it an irresponsible board, and that we despair of seeing any alteration in its line of action. The only method by which any reform can be introduced is for Convocation to refuse to accept any new or supplemental Charter unless it provides that the tenancy for life of a Senatorship be exchanged for a term of years, and that the proportion of elected members be largely increased. But if these provisions were insisted on, the Senate would probably simply drop the application for a new Charter. In March, 1878, when women were admitted to degrees under a supplemental Charter, party feeling ran too high for the graduates to unite in insisting on the retirement of a member of the Senate after a definite period of years, or on an increased representation; but obviously the only hope for any change in the views and plan of action of the Senate lies in an insistence on these conditions. The infusion of new blood from the medical graduate side is imperceptible, and the other faculties do not understand our needs, or if they do they have no sympathy with them. Moreover, the medical influence, such as it is, is declining, and the possibility of active medical teachers being added to the Senate is infinitesimal. In 1863 fourteen members of the Senate had gone through a medical training; in 1884 only eleven have done so. Of these Professor HUXLEY is rather a scientific adviser than a medical graduate, and he is largely responsible for the alterations in the new regulations by which the Preliminary Scientific Examination has been made so stringent and inelastic. Mr. BUSK, Drs. QUAIN, STORRAR, and BUCHANAN, we believe, have never taught in a medical school; Sir WM. JENNER, Sir WM. GULL, Sir G. BURROWS, Sir JAMES PAGET, and Dr. CARPENTER have certainly not done so for many a year; whilst Dr. JOHNSON, who still teaches clinical medicine, would probably allow that he is not conversant with all the details of the student's early education. We need scarcely say that Preliminary Scientific Examinations were not in existence when these gentlemen took their degrees. This explains why the arrangement and the extent of the medical student's scientific studies have been practically turned over to the scientists on the Senate, and why the teachers at the medical schools are in open revolt against the University, and clamouring for a new body in which they will be able to exert some influence, and where regulations destructive to all students except a chosen few will not be made in spite of all their protests. The teachers of Arts and Science are as little satisfied and as inefficiently represented as we have shown our medical teachers to be, and are the leaders in the new crusade for a teaching university in London. Politicians, distinguished amateurs in literature and science, eminent graduates of long standing, and past examiners and officials, with crystallised and unchangeable views of the University as a mere examining board, have been allowed the control of university teaching in the greatest city of the world, and as a result have effaced the influence of the actual teachers and exalted that of pure examiners, until they have banished University teaching altogether.

IT is time that the question of the relation sustained by medical practitioners to their patients received very serious consideration by the profession, and it would, we think, greatly conduce to a proper solution of the growing and pressing problem of "safety" if the ideas of leading practitioners could be discussed at the meetings of some influential Society, and broad principles and rules of conduct formulated for general guidance. The matter is clearly one in respect to which the "men of light and leading" among us might render a significant service by giving the body of medical practitioners the benefit of their advice and example.

It is by no means so easy as it may seem to be to adopt such a mode of dealing with female patients as will meet the full necessities of the case. The medical adviser, and particularly the "family doctor," must needs be in some sort the friend of his patients. Mind is so essentially a body-function that he cannot prescribe for the one without having an insight into the state of the other. Even if it were otherwise, the medical man would inevitably become the friend of his female patients, because women *will*, unless they are kept at a great distance and treated with punctilious politeness only, confide in their medical advisers. Nevertheless, so far as physicians and surgeons are concerned *strictly*, and to the utmost limits of possibility with all practitioners, we are of opinion that it is undesirable for medical men to enter into friendly relations with their female patients. The very fact that a practitioner of medicine must be consulted as to the details of bodily health ought, with any modest woman, to place him on a footing which does not admit of personal or social intimacy. We have no patience with, and little respect for, women who fail to recognise this fact. The medical man may be the confessor, but for this very reason he ought not to be the intimate, of his female patients. A certain sanctity, in a true as distinguished from a canting sense, should attach to the office and surround the personality of the medical practitioner, and it ought to be his aim to preserve this separate and distinctive character throughout his intercourse with those who look upon him as the priest of Hygeia ministering health in the family. The older practitioners were wiser and more circumspect in this matter than those of to-day. They made it a rule never to enter into relations of intimacy with the members of families under their care. If this rule were revived and more commonly observed, we should hear less of charges against medical men alleging familiarity — we do not say *undue* familiarity, because no familiarity whatever of any kind or degree ought to exist; and in the absence of intimacy of any description there could be no ground or pretence for imputation or scandal. With regard to the length of visits, the greatest possible care should be taken. It is a wholly bad practice to allow what ought to be a strictly professional interview to degenerate into a gossiping visit. It is necessary to lay especial stress on this point of prudence. There is obviously too much laxity in respect to the length of visits among medical men. Not one moment longer than the clinical needs of the case require should a medical man, whether

Digitized by Google

physician, surgeon, or general practitioner, remain in the room or the house of his patient. It is injudicious, and tends to detract from the respect in which the medical adviser is held, and to reduce that personal authority or influence upon which his usefulness specially depends, "to unbend," as the phrase goes, and chatter familiarly with those whom it is, above all things, expedient to hold in check. The social position of a practitioner is often equivocal. If his patients are of the lower class, he will either degrade or bring ridicule upon himself by adopting patronising ways if he tries to be familiar with them; while if his patients are his superiors in social station, as must sometimes be the case with men who are in what is called "good practice," he cannot assume airs of familiarity without insolence or effrontery, which may be tolerated, but is never really liked.

We cannot hold the profession wholly guiltless in the matter. There is urgent need of more caution in interviews with patients, and among the measures of safety imperatively necessary are the adoption of a more formally polite manner, with infinitely less hand-shaking and fewer compliments; and a considerable reduction in the habitual length of visits. Upon these two points we must strongly insist. They are required by personal respect and self-preservation, and they are demanded by the dignity of our profession, which we are all pledged to uphold, and which cannot be lowered without being sacrificed.

WITH the progress that is being made in the direction of the etiology of disease, and especially in respect to the infective diseases, there is much room for question how far therapeusis is aided by these discoveries. Even supposing it were proved for all specific maladies that they depended upon the entrance into and development within the body of some specifically endowed parasite, it would still remain a great problem how to arrest its progress. The possibility of employing some agent which can do this or can counteract the changes that the invader sets up in the body receives some countenance from the notable action of a few drugs, such as mercury in syphilis, quinine in intermittent, and perhaps of salicine in rheumatic fever; but as yet very little encouragement has been derived from experiences in the very wide class of infectious disease. And yet on experimental grounds it is well known that there are many substances which act as powerful poisons to microphytic organisms; and theoretically it should be possible to act upon them within the human body. M. CH. BOUCHARD, in raising the question at the recent International Medical Congress, in a paper which has just appeared *in extenso* in the *Revue de Médecine*, said it was folly to argue that such antiseptic medication would have to be pushed until the economy was saturated with the drug, or rather to the destruction of the host before the parasite. It is not necessary, nor is it possible, to attempt to destroy the germs of disease, when these are probably disseminated throughout the body, but he maintains that it is both possible and probable that much can be done to prevent the multiplication of the poison, or to neutralise its effects. It is certainly a fact that almost every antipyretic drug now in use, from quinine and salicine to the last introduced "antipyrin," is also an antiseptic agent, and hence the inference implied by M. BOUCHARD that they owe their antithermic action to a distinct effect upon the actual cause of the febrile state. He cites, with a gravity which can hardly be imitated, the case of a typhoid patient who was nearly poisoned accidentally by carbolic acid; but who, on recovering from the state of collapse produced by the poison, remained free from typhoid symptoms. Here was an instance, he thinks, where the specific fever was aborted by the powerful action of this antiseptic—an experiment which, he wisely adds, it is not desirable to repeat. The drugs that have been prescribed, especially in typhoid fever, with the idea of combating the germ of the disease or neutralising its poison, now compose a formidable category. The very fact that they are so numerous seems to indicate that they have not fulfilled the expectations formed of them. Amongst them all, M. BOUCHARD is most in favour of mercury, and claims the results of the calomel treatment of this disease to be due to its germicide action. He has lately pursued this line of medication in thirty-one cases, two of which were fatal. In eighteen cases salivation occurred after nine days' treatment; the fatal cases had been treated for seven days. This plan of treating typhoid fever, useful as it may be when commenced in the earliest stages, is hardly to be recommended to the practical physician. The evidence that it "aborts" the fever is very small, and if pursued, as its advocates desire, until the patient is saturated with mercury, it is harmful in itself. Convalescence is distinctly retarded by it, relapse is just as frequent. M. BOUCHARD thinks intestinal hæmorrhage is favoured; and amongst sequelæ of a formidable character which arose in cases treated by him were epistaxis, diarrhœa, pneumonia, and endocarditis. So powerful a remedy as this is surely as bad in its effects, and as likely to give rise to as much anxiety, as the disease itself if left to pursue its course with such aid as nursing and diet can afford, with no other medical interference than is required to allay the symptoms as they arise. Yet, in spite of this experience, M. BOUCHARD believes that the antiseptic treatment of typhoid fever is not a merely theoretical notion, but opens up a line of practice which should be diligently pursued.

An endeavour to select the appropriate agent for destroying the special germs of any disease is directed by the aid of experiment; and M. BOUCHARD discusses briefly some of the results obtained by him of the intravenous injection of various substances with a view to check the progress of a disease with the poison of which animals were previously inoculated. Since, however, comparatively few of the diseases in question have yet been shown capable of transmission from man to animals, the results of these experiments are not of a nature to advance knowledge very far. The aims of such an inquiry are no doubt as he describes them—viz., to ascertain what agents are most injurious to the specific microbe of an infectious disease, and at the same time least injurious to man; but as a matter of fact the employment of such remedies in disease is wholly different from their use in the laboratory. Something more, he thinks, may be done by using antiseptic agents locally, without any idea of getting them absorbed into the blood. Such diseases as diphtheria, dysentery, and if Koch's views are to obtain, cholera are open to be dealt with thus locally.

Digitized by Google

But although diphtheria is, we should opine, invariably treated on this principle, it is very doubtful if any reduction in its mortality has been effected thereby. In typhoid fever, M. BOUCHARD has for the past nine years been in the habit of prescribing large doses of charcoal powder, with a view of lessening the dangers due to the presence of putrid sloughs in the intestine. He claims that in cases so treated the stools become inodorous, and are deprived of the alkaloidal substances to the absorption of which may be ascribed the symptoms of "auto-intoxication." Lately, he has combined iodoform with charcoal so as to bring to bear the antiseptic action of the former as well as the deodorant action of the latter; and yet he can claim no greater result than a reduction of mortality from 20 or 15 per cent. to 10 per cent. In fine, without any desire to damp the ardour of those who see in the adoption of the germ theory of diseases a promise of a scientific and rational line of treatment of the specific fevers, we cannot admit that the results of such therapeutic experiments are sufficiently encouraging to warrant a general adoption, or that the employment of "antiseptics" in medicine is a practice wholly free from danger.

MEDICAL teachers and medical students alike await with much anxiety the further action of the Association for promoting a Teaching University in London. As yet there is nothing to announce beyond the fact that a sub-committee is charged with the duty of preparing a report on the subject. This subject has been viewed hitherto very much from the standpoint of those who think it desirable to keep English students in England, and to give London students especially the clinical advantages of that unrivalled clinical field presented by the hospitals of London. It would be difficult to overrate the importance of this advantage. It is not denied even by those who vaunt the advantages of the Scottish universities, that the London hospitals supply the chief material for those discussions which give such importance and effect to our Medical Societies. The youngest disease, recognised, brings out with fresh vigour the ripest teachers, and places medical practitioners in the advantageous position of medical pupils. Let anyone who doubts the enormous advantage of London schools go for a night to a meeting of the Clinical Society or the Medico-Chirurgical Society, and see the rich gathering of cases and the evidence of the clinical detail with which they have been studied. The absence of a teaching university necessitates some of the best students leaving these schools just when they would profit by them, and going to other schools which, with all their advantages, cannot in this respect compare with them. There is another disadvantage in the absence of a teaching university in London which ought to be gravely considered—the entire want of sympathy with students in such an abstraction as a mere examining Board. A university should be a veritable *Alma Mater*. It should be nourishing above all things; but more than that, it should be genial and propitious. It should be encouraging. Adjectives more lucidly descriptive of what the existing University of London is NOT could not be employed. It does not nourish; it chills. It does not encourage; it deters. It is not genial or propitious, but terrible and disheartening. Many a young man gets a blow by striking his head against its examinations, which he is very slow to recover from, and some of the wisest graduates of the University do not hesitate to say so. The student in a true university feels the sympathy of his teachers and the rivalry of his fellow students. There is a domestic stimulus in such an arrangement which may be abused, but which is far too valuable to be dispensed with. The hard, impersonal, exacting, examining institution which now takes the place of a proper university in London must be regarded as a most dreadful device for discouraging; graduation a rock, a pit, a valley of humiliation. This is not what a university is meant to be nor what the nation wants. We would be the last to make graduation too easy, to vulgarise degrees, either in medicine or in any other faculty. In medicine such a course would be a public misfortune. But we want a university in London which will encourage young men to aim higher than for a mere licence to practise, which shall be a centre of healthy and hopeful rivalry in study as well as in the dreary work of examination, and which in its genial and domestic influences shall have some chance of comparing favourably with Cambridge and Oxford, while exceeding them both and the Scottish universities in the scale of its medical opportunities.

Annotations.

"Ne quid nimis."

THE COURT OF EXAMINERS AND THE COUNCIL OF THE COLLEGE OF SURGEONS.

AT the meeting of the Council of the Royal College of Surgeons of England, held on the 13th ult., Mr. J. C. Förster (president), Mr. Savory (vice-president), and Mr. Hulke resigned the office of member of the Court of Examiners. These resignations were accepted, and the vacancies will be filled next Thursday. Mr. Hulke has expressed his willingness to again take office should the Council re-elect him. Mr. Hulke has proved himself so efficient an examiner that his re-election will not only be serviceable to the College, but agreeable to the profession generally. Equally agreeable to the profession, and certainly not less serviceable to the College, will it be if the Council have the courage and grace to fill up the other vacancies by Fellows who are not in the Council. Without any disparagement of those members of Council who are, it is alleged, aspiring to the office of examiner, it may be said that none of them have claims superior to those of three or four of the candidates who are not members of the Council. The action of the Council is anxiously awaited by those who desire to see the College break away from those antiquated traditions which have so long trammelled it and impaired its dignity by perpetuating many of the worst characteristics of the Corporation of Surgeons on the ruins of which the College was originally built. What is urgently wanted in England is a *College of Surgeons* at least as desirous for the encouragement and promotion of the science and art of surgery as eager for the sale of diplomas. This cannot be accomplished as long as the governing body of the College is largely composed of examiners who are tempted to take more direct personal and even pecuniary interest in the sale of diplomas than in the promotion of surgical and biological science.

THE REGULATIONS OF THE COMBINED EXAMINATION.

THE Royal Colleges of Physicians and Surgeons of London have lost no time in issuing regulations for their conjoint examination, which we published last week. Even the dates for the various examinations next year, beginning early in January, have already been fixed. The regulations laid down necessitate a consistent plan of study, and the student should pass the examinations *seriatim* as follows:—Elementary anatomy and elementary physiology, at the end of the first winter session; chemistry, chemical physics, materia medica, &c., at the end of the first or second summer session; anatomy and physiology, in the second winter session; and the remainder of the student's time should be devoted to the practical subjects of his profession—midwifery &c., surgery, and medicine. An important provision stipulates that after once passing in any subject, another examination in the same subject will not be demanded. Lectures on early scientific subjects, such as botany and chemistry, are optional, for certificates of instruction only are required, and only one course of lectures is made compulsory in the other subjects. Particular stress is laid on practical instruction, so that we anticipate that most English general practitioners will consider it necessary to pass the conjoint board. In the published regulations no exemptions are made for a graduate of a British university, but candidates with a colonial, Indian, or foreign qualification will have to pass the second and third examinations. Surely graduates of a university in the United Kingdom will not be asked to again go through an examination in anatomy and physiology, but will be at once admitted to the final examination. One advantage of the conjoint scheme is that candidates run no longer any risk of being referred by one examining board, after having passed a similar examination, by practically the same men at the other board some few weeks previously.

THE COLLEGE OF SURGEONS EXAMINERS UNDER THE COMBINED SCHEME.

AT a meeting of the Council of the Royal College of Surgeons of England, to be held on Thursday next, the 11th inst., the examiners for conducting the examinations under the combined scheme will be appointed. The College of Surgeons will appoint all the examiners in elementary anatomy and in surgery; while the College of Physicians will appoint all the examiners in chemistry (five), materia medica (five), and medicine (ten). Of the remaining examiners, the College of Surgeons will appoint one of the three in elementary physiology, four of the six in anatomy, three of the six in physiology, and four of the eight in midwifery. At the last meeting of the Council, held on the 13th ult., it was resolved not to restrict the selection of the examiners in anatomy and physiology to Fellows of the College, but to extend it to Members also. There is, we understand, a large number of candidates for the five examinerships in elementary anatomy, and for the four examinerships in anatomy. The candidates for the examinerships in elementary physiology and in physiology are, as might be expected, fewer. It may be stated that it is not intended to reappoint the existing Board of Examiners in anatomy and physiology. In place of this it has been decided to employ the examiners in anatomy and physiology appointed by the two Colleges under the combined scheme to carry on the primary examinations for the diploma of Member of the College in the cases of candidates who commenced their professional study before the 1st of October, 1884. A Board of Examiners will, however, be elected from among the Fellows of the College for the Primary Fellowship Examination. The examiners in midwifery will be chosen from among the Fellows of the College of Surgeons or of the College of Physicians. As respects the examiners in surgery, it is intended that, until otherwise determined, the Court of Examiners shall be constituted the examiners under the combined scheme.

THE REVIVAL OF OVARIOTOMY.

IN reference to the address on the Revival of Ovariotomy and its Influence on Modern Surgery, recently delivered by Sir Spencer Wells before the Midland Medical Society, Mr. Lawson Tait, in a letter addressed to us, states that Sir Spencer Wells's claim of having revived ovariotomy between the years 1858 and 1865 cannot in the least degree be substantiated when the facts of the case are fully examined, as, so far as has yet been discovered, the first ovarian tumour removed in England was by the hands of Dr. Charles Clay on Sept. 27th, 1842; all others, with the exception of one by Houston and another by Lizars in Scotland, being clearly parovarian cysts. In 1843 Mr. Aston Key removed both ovaries, and Mr. Bransby Cooper also tried the operation in that year; but it was not till 1844 that there was a successful case in London operated on by Dr. Frederick Bird, followed by one in the practice of Mr. Lane. In the provinces, however, many successful cases had been done. In June, 1848, Dr. Charles Clay published a series of 32 cases with 10 deaths, and in 1857 he had completed 77 cases with 24 deaths, and he continued to operate for many years until he had performed 395 operations with 101 deaths, his total mortality being fractionally above 25 per cent., a mortality almost identical with that occurring in the 1000 cases of Sir Spencer Wells. At the same time the operation was being performed frequently in the large provincial towns of England, but particularly in Manchester by Southam and others, with great success. The only revival, therefore, of ovariotomy, Mr. Lawson Tait points out, which Sir Spencer Wells can lay any claim to is after its temporary decadence for two years and a half in London in the hands of Mr. Baker Brown, and even upon this point the evidence is, says Mr. Tait, by no means satisfactory.

SANITARY CO-OPERATION.

DR. ALFRED CARPENTER read a paper on "Progress and Co-operation in Sanitary Work" on Nov. 27th at the Parkes Museum, Margaret-street. He traced some of the evils which now exist in the sanitary world to the numerous organisations which were trying to direct public attention to the prevention of disease. He asserted that some were established to provide gain to the promoters rather than for the public good. The custom which was growing up amongst men of mark of accepting fees for reports upon sanitary articles was one to be deprecated. Dr. Carpenter asked the members of the Parkes Museum to take a step in advance for the purpose of bringing together the various sanitary associations which were really trying to do good work. He argued that there was no medical association which could take up such a position as was required, because its managers must include non-medical men, such as engineers, meteorologists, land surveyors, and chemists; but, whilst giving honour to the medical profession as the first earnest promoters of sanitary work, they could not for that reason be the managers of an Institute of Health. He then referred to the Social Science Association as the mother of the Sanitary Institute of Great Britain. He thought that the Society of Medical Officers of Health should become a very intimate and integral part of the proposed new organisation, but that the medical officers of health should have a distinct and separate Council for the promotion of their new work and for the publication of their Transactions, but that all the members of that body ought to

Digitized by Google

be members of the chartered body, whilst their work as regards the General Council could be as distinct as that of the Post Office or the Customs in reference to the government of the country. He further urged an amalgamation of the Sanitary Institute of Great Britain with the Parkes Museum and other bodies for the purpose of obtaining a charter to enable them to form a Royal Institute of Health upon a comprehensive basis. An endowment from Government might be asked for to subsidise the new chartered body, though he objected to anything like State interference.

ROYAL DOCTORS.

IT has always been the custom of intelligent princes to acquaint themselves with the studies of their time, and this fact, together with the other advantages of their position, have given them much influence in the advancement of learning. It is new, however, to find them taking a more particular interest in the life-work of their fellow-men, by adopting certain callings as their own, at all events if we except the profession of arms. This latter, from its close connexion with self-preservation alone, other matters being left out of sight, necessarily affects all classes of any people, especially in its earlier history. The peaceful developments of national work, again, belong to an age in which a wiser and more considerate law of comity has succeeded the rule of force, and in which the army has become a highly skilled and heroic form of international police obedient to that law of order. This, at least, is what ought to be, and what we think has begun to come to pass. It is in keeping with this advance in civilisation that members of Royal houses in our day have been attracted to take part in forms of labour which, from their wide application, must often present themselves to the minds of all who have the oversight of nations. The name of Prince Albert Victor will shortly be placed upon the student roll at the Middle Temple, and that of Prince Charles of Bavaria is to be counted among the medical graduates of Austria. It is in various ways advantageous to professional life that Royal and noble men should employ themselves in it, and this is no less true of the art which guards the public health than it is of that which stands in defence of civil rule, or of their sister calling which exists to maintain the purity of our common faith. Let us speak of medicine in particular. It is clear, in the first place, that the adhesion of great names cannot in itself ennoble any profession. On the contrary, a profession exercises its government on all who espouse it. Their work is done by its direction, and it is and must be honoured, not because of those who do the work, but because of the work which is done. This is pre-eminently true of medicine. Not less true is it that success in its aims cannot be said to wait upon or follow the introduction into it of distinguished persons. The Darwinian law has been well illustrated in its history; it has lived through a long and patient evolution, and has come to be what it is by contact with its circumstances, and, so far, with but little State encouragement. How, then, will it benefit by being connected with the first social and political rank? Partly in this, that the example of men whom circumstances have made independent of the primary needs of existence, and who have been surrounded with many of the less fruitful pastimes of leisure, when they earnestly devote themselves to professional work, is valuable to their fellows. It should impress on all others who are similarly engaged that the highest aim of medicine is not mere gain, either of wealth or of social reputation, but that it touches the life and gratitude of persons and of peoples in all their interests, physical, social, and moral. The great importance of hygiene among considerations of national management has been recognised by our institution of a Local Government Board, and by many smaller measures. Other countries have acted in a similar sense, and it is satisfactory to find that, with some at least of those who represent the highest political influence this interest is more than theoretical. We congratulate the Royal doctor and others of like mind upon their choice, and we do not doubt that, exercising as fully as they can the varied powers of their profession, they will find that they also are gainers, and that no vocation educates more equally or even more highly the stronger and the finer faculties of our human nature.

THE BROWN LECTURES.

MR. VICTOR HORSLEY, B.S., M.B., F.R.C.S., will deliver the Brown Lectures on December 12th, 15th, 17th, and 19th, in the theatre of the University of London, Burlington-gardens, at 5 P.M. The subject of the first two lectures will be "The Thyroid Gland, its relation to the Pathology of Myxœdema and Cretinism, to the Surgical Treatment of Goitre, and to the General Nutrition of the Body." The third lecture will treat of Simple Traumatic Fever, based on 100 cases of Simple Fracture. Urethral Fever will be the subject of the fourth lecture. All the lectures will be illustrated by photographs of specimens projected on to a screen by the limelight. Our readers will be interested to know that Mr. Horsley states that he has produced artificial myxœdema in the monkey by the removal of the thyroid gland.

TRACHEOTOMY IN CROUP.

UNDER the above heading, Dr. George W. Gay read an interesting paper at the annual meeting of the American Surgical Society in May last. Referring to the results of medical treatment of "pseudo-membranous laryngitis," he states that in the Boston City Hospital, to which upwards of 400 cases of diphtheria have been admitted within the last eight years, "not a single case of pseudo-membranous laryngitis has ever recovered without an operation." Tracheotomy has been performed 118 times for this disease, and thirty-nine, or just one in three, have been successful. Dr. Gay has himself operated sixty-two times, with success in twenty cases. For these and other reasons Dr. Gay holds that tracheotomy is the best treatment for this disease, and should be resorted to early. He much prefers the high to the low operation, and has no fear of dividing either the cricoid cartilage or the isthmus of the thyroid body. In reference to clearing the bronchial tubes of blood or other secretions, he makes some remarks which are very apposite at the present time. He regards suction as both useless and highly dangerous, and points out that "it is a physical impossibility to suck anything out of the trachea, unless air has a free ingress to supply the vacuum." In such circumstances he forcibly inflates the lungs through the wound, and this is always attended with a forcible return current of air which closes the tubes far more efficiently than any possible suction. In a case mentioned where the bronchial tubes were full of blood, a catheter was inserted into the trachea and air forcibly blown into the lungs, with the result of driving out a large quantity of blood. This plan is one that so long ago as 1867 was practised and recommended by Dr. H. J. Bigelow of Boston. He appears to have taught that the catheter should be passed beyond the blood clot or other obstruction, and that then the escape of the air blown in from the catheter would remove the blood, &c. No doubt this is desirable, but it is not always possible in cases of hæmorrhage into the trachea; and we imagine that in such cases the distension of the lung is followed by such a powerful expiration that this method is of great value. Dr. Beach, in a paper in the *New York Medical Journal* of Nov. 1st, says that the Boston surgeons always carry a catheter in their case of tracheotomy instruments, and that they have complete confidence in this treatment. It is certainly to

Digitized by Google

be preferred to any method based upon suction, not only because of its physiological merits, but because it is simple in its application, and quite devoid of danger.

OUR ARMY.

THE General Annual Return of the Army for 1883, prepared by the Adjutant-General, has just been presented to Parliament. From it we obtain the following information bearing on the health and physique of the troops. The average strength throughout the year, exclusive of officers, was 174,778, of whom 86,357 were serving at home and 88,421 abroad. The deaths among them amounted to 1707, and the number discharged as invalids to 3374, being respectively in the proportion of 9·77 and 19·31 per 1000 of strength; both lower than in the preceding year. The number of recruits enlisted during the year was 61,804, of whom 15,389 were rejected as unfit, being in the proportion of 249 per 1000 inspected; and 1523 were rejected after attestation, raising the proportion to 274 per 1000, or almost identical with that of the preceding year. The total number who joined was 32,924, being 9369 more than in 1882; but to obtain this result it appears to have been found necessary to authorise, during the last eight months of the year, the enlistment of lads at eighteen years of age, and to lower the standard of height to five feet three inches. Nearly 8000 came into the service at the reduced age, the greater proportion being for the infantry of the line. Of the total number that joined, 629 per 1000 were under twenty years of age. Compared with the preceding year, the returns show a decrease in the courts-martial for drunkenness of about 2 per 1000, in the number of men fined for that offence of 7½ per 1000, and of cases of drunkenness in which a fine was inflicted of nearly 10 per 1000 of the strength. The courts martial for drunkenness were in the proportion of 16 per 1000 of the strength among the troops serving at home, and 22½ among those serving abroad. The Return does not furnish similar information with regard to the fines. The nationalities of the men serving at home and abroad on Jan. 1st, 1884, were: English, 722 per 1000 of the force; Scotch, 79; Irish, 186; colonial and foreign, 13. Compared with those serving on Jan. 1st, 1874, there is an increase of 43 per 1000 of English, and a decrease of 4 per 1000 Scotch, and of 49 per 1000 Irish soldiers. The returns continue to show an increase in the numbers reported as possessed of "superior education." The proportion amounted on Jan. 1st, 1884, to 783 per 1000 serving, an amount which leads us to doubt whether the test is a very strict one, or, if so, whether it is stringently applied.

GASTRITIS FAVOSA: A NEW DISEASE.

AT the meeting of the Vienna Imperial and Royal Society of Physicians on the 28th ult. Professor Kundrat exhibited specimens of a unique kind. The case was one of favus universalis which had given rise to an abscess of the thigh, and had terminated fatally from severe gastro-intestinal disorder marked by an uncontrollable diarrhœa. Numerous erosions mingled with diphtheritic swellings were found in the mucous membrane of the stomach, and the intestines contained some foul putrescent masses and much mucus. Professor Kundrat at once declared the diphtheritic swellings to be due to the favus fungus, a view which was confirmed on microscopic examination. This is the first recorded instance in which the mucorineæ have been the cause of death, as it is the first of favus of the stomach and intestines. Indeed, the naked-eye appearance of the tumours in the stomach closely resembled the favus cups on the skin, and the fact that but little of the fungus was found in the intestine was explained by Professor Kaposi by their having undergone putrefaction in the bowel. The patient had previously been shown to the Society by Professor Kaposi as a rare instance of favus, which covered the entire body, affecting even the finger-nails (attributed to his habit of scratching himself constantly). Favus of the stomach is as unknown a condition in animals as it is in man; at any rate, Professor Csoker, of the Vienna Hospital for Animals, stated that it never occurred in cats, although these animals frequently eat rats infested with the fungus. Professor Bamberger suggested that in this case the gastric mucosa was in an unhealthy condition at the time of infection, thereby affording a favourable nidus for the growth of the fungus. It must be borne in mind that the mucorineæ, unlike the schizomycetes, can thrive in acid liquids, and may therefore grow with impunity in the stomach. The case is of great importance, as showing that if they do gain access to the interior of the body, these fungi may be a source of danger and lead to a fatal result, thereby disproving the usually accepted notion of their harmless character.

WELLINGTON COLLEGE.

THE melancholy illness which during the past week has terminated two valuable lives at Wellington College appears to be a continuation of similar sad events occurring during the past four years. One of the pupils at the College, Percy Edmund Leopold Cust, aged fourteen, the orphan child of a distinguished English family, whose services to the country had already secured for him marks of Royal favour (for he was page of honour to the Queen), which in due course must have ensured for a youth of his promise still greater honour and dignity, died on the 24th ult. The other death quickly following this was that of the Rev. C. H. Lane, Bursar and Tutor to the College, and formerly of St. Catherine's College, Cambridge. Both were stricken down in the fulness of health, strength, and active life, and on the fourth day from the commencement of their illness it proved fatal. The nature of the disease was such that speedy interment had to be effected. Our readers will remember that in January and February of the present year we published a lengthened correspondence between the Hon. Colonel Talbot (Vice-President of the College), Mr. Barford (who for more than twenty years had been medical officer to the College), and Mr. Baldwin Latham (who had been engaged to carry out an improved system of sewerage, sewage irrigation, and water-supply). While, on the one hand, the Vice-President, on behalf of the Governors, admitted the existence of some local cause producing a series of deaths from "blood-poisoning," Mr. Baldwin Latham, on the other, contended that his system of sewerage, sewage irrigation, and improved water-supply had effectually removed these local causes of disease for the future. That the Governors of the College were earnestly determined to effect this at any cost was evident at the time, nor could otherwise be expected from so distinguished a body. Mr. Barford took exception to Mr. Baldwin Latham's system of sewerage, irrigation, and water-supply, pointing out at the time that the engineer had scarcely touched the fringe of the difficulty. Hope was held out that thenceforth grave and fatal illness would be banished from Wellington College. Mr. Barford felt justified from his long experience in predicting otherwise, and the sad events of the past week appear to leave but little doubt that his views were correct. The Governors of Wellington College must feel that, earnest and great as their efforts have been to rescue the institution from the suspicion with which it had come to be regarded, two fatal cases of illness in one week cannot do otherwise than cause anxiety among the parents of the boys committed to their charge. His Royal Highness the Prince of Wales, as President of Wellington College, is not likely to permit such events to pass without a full and impar-

Digitized by Google

tial public inquiry being made, having equal regard to the medical and the sanitary aspects of this question. If Wellington College is to be visited perennially by disease and death, the question may well be asked, What is to be its future?

SHOOTINGS FOR LUNATIC ASYLUM PATIENTS.

A PARAGRAPH in the *New Moon* of October, 1884, a periodical published at the Dumfries Asylum, tells how 2000 acres of moor have been taken for shootings for the patients, and gives the name of a patient who was out shooting, and the bag made. The advisability of placing loaded guns in the hands of patients who are under certificates of lunacy, and detained as inmates of an asylum, is a question open to a considerable amount of diversity of opinion. The uncertainty of mental disease is known, also the frequency of sudden relapses in convalescents, and the impulsiveness of action in such cases is recognised. The physician who prescribes shooting for his insane patients must have a thorough belief in his knowledge of his cases, and in his own judgment. It is to be hoped that the attendants who accompany the shooting parties are well paid for the risks they run, and have their lives insured in accidental offices. Though the terms of the charters of most of the endowed asylums are not generally known, yet the tenour of the benefaction, in most instances, was intended to enable sufferers from mental disease, educated though poor owing to the calamity of their diseases, to enjoy medical treatment and social comfort suitable to their former position. Very properly, there have been of late years advances in the ideas of social comfort, and seaside houses and addenda of like description are now connected with asylums of this class. Occasionally remarks have appeared pointing out that some endowed asylums, neglectful of their true work, lay themselves out to attract rich boarders. Trustees and directors of endowed asylums should clearly keep before them the beneficent aims of original founders, and should not in any way be themselves the means of bringing an inquiry on themselves such as has been the case in some other endowed charities.

REGINA v. C. F. J. B. BRIGGS AND E. BRIGGS.

IN THE LANCET of Nov. 29th there appeared a letter from Mr. T. Bond, F.R.C.S., calling attention to the above case, which was tried at the last Nottingham assizes, when the male prisoner was sentenced to twenty years' penal servitude. We have now gone carefully through the depositions, and, much as we regret to challenge the accuracy of the conclusions drawn by the medical witnesses, we feel bound in the interests of justice to enter a protest against the statement that "death had been induced from want of sufficient food," and that "the absence of fat indicated a want of sufficient food." It appears that the deceased, Thirza Briggs, the wife of the male prisoner and the daughter-in-law of the female, had been ailing for some time, and that she had frequently complained of unkind treatment at the hands of both prisoners. On one occasion she wrote a letter to a witness at the trial, saying that she was being starved. Evidence was also adduced that she frequently partook of nourishment provided by the neighbours, and that too until a short time before her fatal illness. Concerning the general facts of the case, as sworn to before the magistrates and at the assizes, we have little or nothing to say; but we contend that the symptoms observed during life, and the post-mortem signs noticed by the medical men who conducted the autopsy, were not inconsistent with death having arisen from natural causes. "On Sept. 28th deceased fell down in a fit, and on Oct. 3rd she died comatose." The fit was believed by the medical attendant to be apoplectic in nature. There was paralysis of the *left* arm and leg. Post mortem the *right* side of the brain was seen to be congested, and two tablespoonfuls of cloudy serous fluid were removed from the base of the skull. Finding no trace of hæmorrhage in or upon the brain, the doctors concluded that the cause of the apoplexy was the pressure of the fluid upon the medulla oblongata and pons Varolii, and that the "serous effusion" was the result of starvation. In the first place, we join issue with the doctors on their interpretation of the facts observed. The fluid seen at the base of the skull was probably what had escaped from the ventricles during removal of the brain. The quantity, too, was, in our opinion, quite insufficient to bring about fatal compression. It is generally conceded that a slight increase in the cerebro-spinal fluid, such as was found in this case, is rather evidence of the mode of dying than of the cause of death. One thing is quite clear, it did not account for the unilateral paralysis. What, then, was the cause of the *left* hemiplegia? We will answer this question by another, What was the cause of the congestion of the *right* side of the brain? The deceased, be it remembered, was, from her own account, the subject of rheumatism, and at her age she was not unlikely to have cardiac valvular affection. We are aware, on the other hand, that the heart was declared to be healthy—that there were no vegetations on the valves. Still the origin of the "brain trouble" requires explanation, and we maintain that, in the absence of hæmorrhage, the cause was to be sought in the cerebral arteries, which were probably plugged with emboli or thrombi. With regard to the intussusception of the small intestine seen at the autopsy, that was probably a post-mortem phenomenon. We do not cast the slightest imputation upon the credit of the medical men, nor suppose that they acted other than from the dictates of conscience; but we prefer sooner to "believe a dozen honest men deceived than a law of nature reversed." If the conviction, and its consequent severe sentence, were founded upon the post-mortem testimony, we fear that there has been a serious miscarriage of justice, and we hold that the Home Secretary would be well advised to further investigate the case.

MEDICAL EDUCATION IN THE UNITED STATES.

THE mushroom-like growth of medical schools in the United States is a matter of concern, and almost of shame, to all who value the public health or the dignity of the medical calling. Our own Legislature is so nearly helpless at present in regard to medical education, and the bodies which test it, that we speak with some moderation. But in the United States things are much worse. In that "unhappy country," as Artemus Ward would say, every State does that which is right in its own eyes, and the greatest laxity prevails in the conditions of medical licensing. An important Report has lately appeared on the subject from a Commissioner of Education, General Eaton, which at least has the advantage of directing attention to the system of medical education from colonial times down to the present. The steady increase in the number of institutions, instructors, and students is ominous. Thus, in 1873, the number of institutions was 94; in 1882, 134. The number of instructors in 1873 was 1048; in 1882, 1946. The number of students in 1873 was 8681; in 1882, 15,151. The great evil there is as here, only greater—the number of competing schools and the tendency to lower or dispense with the entrance examinations. General Eaton says, "They do not like to establish effectual entrance examinations (which might force some candidates to defer the study of anatomy and chemistry until they had mastered the simpler mysteries of reading and writing), because they do not want to limit the number of doctors by artificial regulations." This is a curious view of entrance examinations, that they are "artificial regula-

Digitized by Google

tions." The expression is quoted by General Eaton from the address of a widely known and much respected teacher and author. The old idea that a physician should be a man of letters and learning as well as of art has been there dissipated by the action of the competing schools. We must not omit to notice honourable exceptions given by General Eaton, the University of Pennsylvania Medical School, Harvard, the Chicago Medical College, and the New York Women's Medical College. In these institutions preliminary education is courageously enforced and more elaborate courses of study are required. We urge on the governing bodies of the United States the immediate importance of this question in the interest of the citizens. It is no mere question of professional jealousy. It is a life and death matter.

THE HEALTH OFFICERSHIP TO NOTTINGHAM.

THE appointment of a medical officer of health to the borough of Nottingham is now engaging the attention of the council and citizens of that town. A number of candidates have come forward for the post which Dr. Seaton has ably filled for some years, and which is now rendered vacant by his appointment to the health officership to Chelsea. Among other candidates are Dr. B. A. Whitelegge and Dr. Handford. Dr. Whitelegge, who is a graduate in medicine and science of the University of London, has devoted much time to the study of public health questions, and is well known for his excellent work in connexion with the Mansion House Council on the Dwellings of the Poor. If elected, he would bring to bear upon his duties an unusually well-trained mind and considerable experience. Dr. Handford, who is a graduate of Edinburgh, has also special sanitary knowledge, and is well known to many of the residents of Nottingham.

OVER-PRESSURE IN SCHOOLS.

THERE is more than a probability that the inquiry concerning this subject, instituted most unwillingly by the London School Board, will be either burked or conducted with closed doors, so that no good result can be obtained so far as the movement as a whole is concerned. We anticipated this miscarriage of prudence and honesty, and therefore are not in the least degree surprised by the news that reaches us. The Educational Department of the Privy Council will, of course, be quite contented with any arrangement which will secure a report as—well, let us say as little—satisfactory as that of Mr. Fitch. Nevertheless, the question which has been so boldly and effectually raised by Dr. Crichton Browne will not be brought to an issue by such trifling; and we venture to suggest that, in the interests of common sense and self-respect, the School Board for London should not allow its committee to play the part of cat's paw to any Department.

WASHHOUSES AND INFECTION.

A MEMBER of the National Health Society has rendered good service to the cause of sanitation and to his fellow citizens in a letter advocating the thorough disinfection of the clothes of cholera patients in the washhouses to which they may be sent when soiled. He draws attention to the statement in a daily paper, that no such measures have been instituted in Paris up to the present time, and quotes the experienced testimony of Professor Tommasi Crudeli in proof that very simple means applied to this purpose sufficed to limit the spread of the epidemic in Palermo in 1866. In Paris, it is stated, the clothing is brought from the foci of disease to the laundry, is washed in water which is merely warm, and without any further process besides that of drying thoroughly ?) is returned in the very vans by which it came. The last point indicates another glaring error. We understand, moreover, that it is not, except in the present instance, a Parisian fault, but that even in London clothes disinfected, for example after fevers, by professional disinfectors, are removed impure and restored after purification, sometimes by one and the same vehicle. We may be allowed to question whether this conveyance is cleared of all contagion after every journey. The suggestion as to the due cleansing of laundry clothing is a valuable one in connexion with a possible invasion of our own country by cholera. The means to be employed should be such as to ensure perfect dryness, which alone, according to Dr. Koch, is sufficient to kill the germ of contagion. Dry heat of a high degree may best be relied on for this purpose, and with this we would strongly advocate the combination of an additional security by antiseptic fumigation. The clothes should be subjected to the process before washing as well as after it, since the protection of laundry-women must not be overlooked. The careless employment of a few carts for indiscriminate carriage requires no words of ours to indicate its remedy.

LOW REMUNERATION OF MEDICAL OFFICERS OF PROVIDENT DISPENSARIES.

THE supporters of the West Cheshire Provident Dispensaries, including Mr. Vacher, the borough medical officer of health of Birkenhead, seem well satisfied with the progress of the institution. The number of members increases, as well as the amount of medical work. What continues to be doubtful is the advantage to the medical officers. This point seemed to weigh on only one of the speakers, at a recent meeting, the Rev. Canon Robson, who said "he was afraid their medical staff in Birkenhead did not get much out of the institution for their work for the good of the people, but he hoped its increasing success would compensate them." We hope so, too. A provident dispensary that does not pay its medical officers well is not worthy of the name.

LAYING STRAW IN THE STREETS.

WE regret that it should have been deemed necessary to suggest to parochial authorities the opportunity which exists for making a show of power, and thereby endangering the life, it may be, of some sufferer, by refusing to permit the laying of straw in the streets. This is one of those short-sighted interferences with the liberty of the individual which do infinite harm. Granted that there may have been a few isolated instances of needless straw-laying, far less injury was done by such excess than will be done by the delay now instigated. We repeat that we exceedingly regret the suggestion which has been made by Mr. Blyth, the medical officer of health for Marylebone. It will be productive of endless and wanton injury to poor sick folk, who in the streets of London can scarcely enjoy an hour's repose by day or by night. Whenever and wherever a registered medical practitioner recommends that straw should be laid down, permission ought to be granted without delay or objection.

REMARKABLE CASE OF HYPERTROPHY.

AT the Pathological Society, on Tuesday last, Mr. F. Treves exhibited an extraordinary living specimen of congenital deformities. The case was that of a man aged twenty-four, who was born at Leicester, where he was exhibited as the "elephant" man, and there is a certain amount of reason for such designation. The enormous hypertrophy of all the soft and osseous tissues of the right upper extremity formed the strongest contrast with the normal left limb. Projecting buttresses of hard bone distort the normal shape of the head so as to give a hideous expression to the countenance, which is not

Digitized by Google

made less repulsive by the great hypertrophy of the right superior maxilla, which almost obliterates the oral cavity, though the patient stated that he could swallow easily. Large pendulous masses of fibro-fatty tissue, with hypertrophy of the skin, hung down in huge folds from the back and buttocks; in many parts the altered skin was decidedly papillomatous. The right lower extremity was out of all proportion to the left. The man's intelligence was apparently up to the average, so that he was not, like Caliban, "as disproportioned in his manners as in his shape." Mr. Hulke spoke of a case recorded by Mr. G. Pollock, in which large pendulous masses gave the body of a man a most ponderous appearance. Virchow, in *Die Krankhaften Geschwülste*, has pictured similar deformities.

THE HOSPITAL SUNDAY AND SATURDAY FUNDS.

THERE are one or two satisfactory features about the Report of the Hospital Sunday Fund for the current year. The first is the increase of 108 in the number of collecting congregations as compared with the previous year. Another is the contribution of £4500 from the Prince of Wales, as President of the International Health Exhibition. We may be excused for singling out another noble feature of the collection of 1884—namely, the contribution of £1087 by one congregation, that of Canon Fleming, of St. Michael's, Chester-square. We cannot doubt that such a collection implies not only generosity on the part of the congregation, but trouble and care on the part of the Canon to facilitate the action of such generosity. The example is one that cannot be too faithfully followed by other congregations. The Hospital Saturday Fund awards have been made, and are published. The sum distributed, £9000, we are glad to say exceeds that of the previous year by £750. Amongst the principal awards are the London Hospital, £555 1*s.* 6*d.*; Brompton Hospital for Consumption, £650 4*s.* 8*d.*; St. George's Hospital, £291 5*s.* 8*d.*, &c.

NEEDLESS NOISES IN LONDON.

AT the very time when a medical officer of health is, we regret to find, "putting up" local authorities to refuse permission for laying straw in the streets for the salvation of the sick who are racked on their beds of suffering by the rattling of cabs and waggons, a layman has started the excellent notion of forming a fund for the prosecution of engine drivers, or their employers the companies, for needless whistling. A contemporary, applauding the idea, and predicting that a fund will be quickly accumulated, suggests that the area of reform should be extended, and that the incessant ringing of church bells should be put down with an equally strong hand.

GERMAN COMMISSION ON VACCINATION.

WE learn that the German Commission appointed to inquire into the subject of vaccination has, with the exception of the three members opposed to vaccination, unanimously declared for vaccination with humanised lymph rather than with that from the calf. At the present moment we do not know upon what grounds this preference depends, but we assume that the fact is recognised that *direct* vaccination—i.e., vaccination with lymph which is not stored—"takes" far better, and therefore gives much more protection against small-pox, than vaccination with stored lymph. Vaccination with calf lymph throughout the country must necessarily be performed with stored lymph; but direct arm-to-arm vaccination with humanised lymph is a possibility everywhere. Calf lymph has its use in enabling practitioners to renew their stock, and also in giving opportunity for the direct vaccination of numbers of persons in large centres of population. If in future it can be found that calves can be inoculated with small-pox virus and the virus modified by such transmission through the animal, it is probable that the use of calf lymph will serve this purpose more than heretofore.

WILFUL "EXPOSURE OF SMALL-POX."

WE should like to see the opinion of a court of justice taken upon the folly of compelling a jury to view the body of a patient who died of heart disease when suffering from small-pox at the Western Hospital, Fulham. It would be interesting to ascertain whether or not the act of exposing the body of a small-pox patient to the jurymen was a breach of the Act which imposes a fine for the exposure of a patient suffering from small-pox in any public place. A hospital is not public, but if the public be brought into a hospital that makes it a public place. The inquest was wholly unnecessary. We think the jury or some of its members should try the case.

THE LATE DR. MAHOMED.

WE understand that it is proposed to hold a representative meeting at Guy's Hospital on Wednesday afternoon, Dec. 10th, at 4 P.M., with a view of concerting measures for giving substantial expression to the appreciation in which the memory of the late Dr. Mahomed is held by those who have been his colleagues, fellow-workers, and friends. It is earnestly hoped that as many as possible will attend.

ENTRIES AT THE DUBLIN MEDICAL SCHOOLS.

THE total number of students who have entered for the session 1884–85 amounts to 790, being a decrease of nine as compared with last year. Of the five medical schools, two show an increase, two a decrease, and one has exactly the same number as last session. The following are the returns:—School of Physic, Trinity College, 229; Ledwich, 213; Catholic University, 120; Carmichael College, 117; Royal College of Surgeons, 111.

BACILLI IN SYPHILIS.

THE discovery of bacilli in syphilitic lesions is announced by Dr. Lustgarten (*Wien. Med. Wochensch.*, No. 47). His researches, which were made in Weigert's laboratory at Leipsic, consisted in a special method of preparation and staining of sections of primary chancres and a gumma. In all were found isolated or in small groups, slender, straight or slightly curved bacilli, much resembling tubercle bacilli. The organisms were embedded within swollen lymphoid cells, and exhibited transparent spots, which resembled the "spores" of Koch's tubercle bacillus.

CASE OF EXCISION OF TUMOUR OF BRAIN.

THE latest information about this case is that the surgical condition of the wound is causing some anxiety; otherwise the man is in a satisfactory state. He has not had any violent pain or convulsion as before the operation, and his intelligence is perfect.

A MONUMENTAL brass to the memory of the officers, Army Medical Department, and non-commissioned officers and men, Army Hospital Corps, who lost their lives in Egypt in the years 1882–83, has just been erected in the Chapel of the Royal Victoria Hospital, Netley. The Memorial was raised by subscription among those officers of the department and corps who served in Egypt during that period. Messrs. Mathews and Hodgson, of Regent-street, London, executed the work.

Digitized by Google

A MOVEMENT is on foot among present and past medical students of Cambridge University, and more especially those connected with Addenbrooke's Hospital, to raise a permanent testimonial to Dr. George Edward Paget, F.R.S., Regius Professor of Physic, late President of the General Medical Council of Education and Registration, in recognition of his great services to the profession in general, and to that department of university study in particular. It is proposed that the testimonial shall take the form of a statue, with a bust of the professor, to be placed in the grounds in the front of Addenbrooke's Hospital.

IT appears that the reports of the fatal epidemic which recently broke out in some remote counties of South-West Virginia and East Kentucky were not exaggerated. According to the latest reports it is estimated that 2000 persons have perished from the disease, which was, however, not of a contagious character. The use of water unusually impregnated, in consequence of evaporation, with salts and mineral products, is believed to have been the cause of the disease.

ON the 30th ult., the death occurred of Sir Alexander Grant, Principal and Vice-Chancellor of the University of Edinburgh, from an apoplectic attack with which he was seized on the 29th ult. Sir A. Grant was born in New York in 1826, and was educated at Harrow and Balliol College, Oxford, afterwards becoming a Fellow of Oriel College. In 1856 he succeeded his father as ninth baronet.

THE deaths are announced of two renowned physiologists—viz., Prof. v. Vierordt of Tubingen, and Prof. von Wittich of Königsberg. The former had long given up teaching, but it is only recently that the latter resigned his chair owing to ill health.

AT the quarterly general court of the Governors of the Middlesex Hospital, held on the 27th ult., Dr. David W. Finlay was elected additional full physician to the hospital. This will create a vacancy in the staff of assistant physicians.

DR. KOLBE of Leipzic, whose name is associated with the chemistry of salicylic acid, has recently died.

PROFESSOR C. Y. PEARSON has been appointed lecturer on Forensic Medicine in Queen's College, Cork.

CHOLERA is stated to have broken out in the French fleet blockading Formosa.

MR. FREDERIC S. EVE, F.R.C.S., has been elected Assistant-Surgeon to the London Hospital.

SANITARY ASSURANCE ASSOCIATION.—On the 3rd inst. Dr. Norman Chevers delivered an address at the Parkes Museum, W., on the objects of the Sanitary Assurance Association. Dr. Chevers urged that the sanitary condition of London was such that no householder should be satisfied without the assurance of some competent authority that his dwelling, whether a palace or a cottage, was free from drain contamination. He expressed an opinion that consumption was hereditary principally because successive generations neglected to remedy the sanitary defects from which their forefathers suffered, and pointed out that unless dwellings were properly disconnected from the main sewers, such sewers might prove to be of the greatest possible danger to the whole community in case of any epidemic. Sir William Robinson, Surgeon-General Perkins, M.D., Mr. Mark H. Judge, A.R.I.B.A., and others having spoken, votes of thanks were passed to Dr. Chevers and the chairman, and the meeting terminated.

Pharmacology and Therapeutics.

THALLIN.

THE industry of continental chemists in the application of the synthetical methods to the formation of new compounds has brought to light a new antipyretic agent, which appears to have been used successfully in a large number of cases in the clinic of Professor Nothnagel. It has the constitution of a secondary chinoline base, being one of a number of chinoline derivatives prepared by Professor Skraup, and is represented by the systemic name, "tetrahydroparachinanisol." The salts of this base, which have an acid reaction, are freely soluble in water, and have the property of forming green compounds when treated with solution of ferric chloride and oxidising agents. On account of this peculiarity, the cumbrous systemic name has been dropped in favour of the shorter designation, "thallin." The hydrochlorate, sulphate, and tartrate of thallin and the hydrochlorate of ethyl thallin are the salts that have been employed, and these are said to show great antipyretic activity in doses of quarter, half, and three-quarters of a gramme, a point in which thallin would seem to compare favourably with some of its competitors. The lowering of the temperature is said to take place gradually and to last a considerable time, whilst it is not accompanied by any secondary disturbances. Thallin can be conveniently administered in wafers containing a quarter or half of a gramme of the sulphate. Two other chinoline derivatives have been experimented with; one of them has but slight antipyretic properties, whilst the other was fatal to guinea-pigs in doses of from ·2 to ·6 gramme, violent tetanic seizures being excited.

ALKALOIDS OF QUEBRACHIO.

For a long period of time the inhabitants of South America have employed quebrachio on account of its febrifuge, tonic, antiasthmatic, and astringent properties. White quebrachio, of which three species are recognised, is a tree belonging to the family of apocynæ which abounds in the Argentine Republic. Penzoldt in 1879 proved that a decoction of the bark slowed the pulse and diminished the frequency of respiration, but he noted no antipyretic effects. Berthold and Picot confirmed these results. The value of one of the alkaloids, aspidospermine, discovered by Fraude, in relieving dyspnœa has been corroborated by a number of independent observers. Hesse has determined that there are as many as six alkaloids in the aspidospermine of commerce. MM. Eloy and Huchard have separated the alkaloids in a state of purity, and have made a series of thirty-six physiological experiments in reference to their antithermic action. The experiments were made on rabbits, guinea-pigs, and dogs by means of subcutaneous injections. All the alkaloids were found to exercise a marked antipyretic action. A remarkable effect was also observed to occur in the colour of the venous blood, which became of a vermilion red tint like that seen after poisoning by prussic acid and carbon monoxide. Subcutaneous injections of from ·10 to ·20 centigramme of the hydrochlorate of aspidospermine in patients suffering from typhoid fever appeared to lower the temperature in cases where quinine had had no effect. Lactate of aspidospermatine is a more powerful alkaloid in reducing the temperature than hydrochlorate of aspidospermine; the sulphate of hypoquebrachine and the lactate of quebrachine are still weaker antipyretics.

VAPOUR OF GLYCERINE.

According to an account in the *Gazette Médicale de Nantes*, M. Trastour has employed with great advantage the vapour of glycerine whenever a distressing or frequent cough has had to be alleviated. The remedy is very simple in application. About fifty to sixty grammes of glycerine are heated in a porcelain capsule by means of a spirit lamp; a large volume of vapour is thereby disengaged, and should be breathed by the sufferer. Glycerine, in which carbolic acid has been dissolved, may also be employed. The cough of phthisis and the irritation in the throat of many complaints afford proper trials for these remedies.

HYDROCHLORATE OF PAREIRINE.

In an interesting memoir on the therapeutic value of certain drugs contained in the Brazilian Pharmacopœia, M. Ferreira has drawn attention to the value of hydrochlorate of pareirine in the treatment of cases of paludism

Digitized by Google

which prove refractory to the use of quinine. The dose of two grammes a day of the salt is proposed for chronic cases dependent on latent ague, and the dose may be doubled where the acute stages have to be dealt with.

CARBOLIC ACID IN AGUE.

The recommendation of a more frequent trial of subcutaneous injections of a 1 per cent. solution of carbolic acid was made recently by M. Dieulafoy at the Société Médicale des Hôpitaux. He had employed the method in an obstinate case of tertian ague. The remedy, which is by no means new, is employed twice or thrice daily in doses of from two to three centigrammes of the solution above indicated.

TREATMENT OF INTESTINAL OBSTRUCTION.

A DISCUSSION AT THE

LIVERPOOL MEDICAL INSTITUTION.

Dr. GEE, President, in the chair.

DR. HYLA GREVES opened the discussion by reading the notes of a case of intestinal obstruction by an abnormal appendix vermiformis, which was under his care at the Children's Infirmary, and which was operated upon by Mr. R. N. Pughe, and recovered. C. B——, aged six, a strong healthy lad. He had frequently suffered from attacks of constipation, which sometimes lasted a week, and on one occasion a fortnight, without a motion. On July 6th he was seized with violent pain in the abdomen, vomiting, with absolute constipation. Purgatives were administered without effect. He was brought to the Infirmary for Children on the fourth day. He was then suffering from severe pain in the right iliac region, where there was a distinct and localised feeling of resistance, which was quite resonant on percussion. No hard tumour could be felt. Rectal examination revealed nothing. He vomited everything. Constipation was absolute. An enema (given in the out-patient room) failed to give relief. On consultation it was decided to perform abdominal section. This was done on the fifth day of obstruction by Mr. Pughe. About twelve inches of small intestine were found to be tightly strangulated by an abnormal appendix vermiformis, whose free end had become fixed to the iliac fossa, forming a complete ring, through which the small intestine had slipped and become strangulated. This ring was divided, and strangulation relieved. The intestine was deeply congested and distended; there was no peritonitis, however. Pain and vomiting were at once relieved. The patient was fed entirely on filtered beef-tea and Valentine's extract. No milk was allowed. On the fifth day after the operation the bowels acted spontaneously for the first time. He was then allowed a little solid food. He did not have a single bad symptom after the operation, and he made a perfect recovery. When last seen, on Oct. 25th, he was in robust health. In the treatment of the early stages of acute intestinal obstruction Dr. Greves deprecated the employment of purgatives, abdominal taxis, insufflation, &c. Enemata, if used at all, should only be employed at the commencement of intussusception when the diagnosis was clear. He insisted on the necessity of withholding all solid food, including milk. Filtered beef-tea in small quantities, ice, &c., are amply sufficient to maintain life during the anxious period. Morphia should be given in proportion to the pain; unless the diet be strictly limited, opium is of no use. It is best given by the mouth, unless there be much vomiting; in the latter case morphia subcutaneously administered is better. A surgeon should be consulted early; advice is generally called in too late for any chance of operating successfully. When the symptoms of absolute obstruction exist, and their onset is sudden, a definite diagnosis as to the actual cause of the obstruction is not a *sine qua non* for operative interference. Therefore when, in spite of a short trial—e.g., two or three days—of palliative treatment, a strictly limited dietary, opium, raising of the foot of the bed (to encourage the gravitation of fluid towards the thorax and away from the site of strangulation), &c., the tongue becomes dry and brown, vomiting frequent and persistent, the pulse, though perhaps decreased in frequency, becomes weaker, abdominal section should be performed, care being taken to guard the patient against shock during the operation by protecting the intestines with hot antiseptic cloths, and maintaining the air of the operating room at a high temperature, &c. The after-treatment must resemble in its essentials that recommended for the earlier stages. No solid food by the mouth till the bowels have acted spontaneously should be taken.

Dr. WATERS remarked on the importance of the subject and the interest attaching to all cases of intestinal obstruction. He dwelt on the value of correct diagnosis, on its extreme difficulty in many cases, and its impossibility in some. The man who would hastily assume that obstruction depended on this or that cause, without very careful observation, would be liable to commit a gross error. He thought that in all cases where surgical interference was not directly indicated medical treatment should be fairly tried. The treatment which he adopted was absolute rest, complete or almost complete abstinence from food, and the exhibition of opium and belladonna. These latter he generally gave by the mouth, but in some cases subcutaneous injections might be preferable. This treatment he continued till the acute symptoms subsided, and then he gave large enemata. He deprecated very strongly the use of purgatives. Under such treatment as he had referred to a large number of cases would recover. If it failed, the failure would be due to the presence of some organic lesion. Allusion had been made to the gravity of fæcal vomiting as a symptom. It did not necessarily indicate organic obstruction. In a case recently under his care the vomited matter had a distinctly fæcal odour. The vomiting ceased after the exhibition of a dose of calomel, and soon after the bowels acted. The patient recovered. Dr. Waters mentioned a case, illustrative of the great difficulty of diagnosis, in which no sign of organic obstruction could be made out, and when after death it was found that rupture of the colon had taken place with escape of the intestinal contents into the structures behind it.

Mr. BANKS considered that two serious difficulties would always present themselves in connexion with the question of operation, the first being difficulty of diagnosis. After eliminating the more obvious causes of obstruction, such as impaction of fæces, intussusception in young children, and cancerous or other growths in the adult, capable of being felt, he believed that in all the other cases anything like a certain diagnosis was impossible, and that in his own instance he now, after considerable experience, felt no more certainty about pronouncing upon the nature of the disease than when he first began. In the only case in which he had operated the symptoms pointed in a very clear manner to one affection, but when the abdomen was opened a different and totally irremediable condition was found. The second difficulty consisted in the fact of spontaneous recovery under the opium, rest, and starvation treatment, which had now for many years been the recognised practice. As everyone of any experience knew recoveries took place under such treatment after obstruction had existed for weeks, so that he felt that an indiscriminate employment of the operation would result, for the most part, in the finding of conditions which either could not be relieved or which in time would have relieved themselves if left alone. On the other hand, while deprecating rash interference, he freely admitted that the post-mortem table every now and then showed us, to our great mortification, conditions which might have been relieved by early operation. At the present moment our pressing urgency was more knowledge in the way of clearly defining this limited class of cases. While he trusted that time would improve our means of diagnosis, at present he would only operate, to put the matter in the simplest possible way, in the case of a child or healthy young adult, suffering from all the symptoms of an acutely strangulated hernia, but in whom a hernia could not be found.

Mr. H. O. THOMAS, after expressing satisfaction at the mode and result of the medical and surgical treatment adopted in the case related to the meeting, then offered as a solution of the propositions laid before the members the following. That primary treatment should be directed according to the natural attempts at resolution, which in essence was similar to the Sydenham method; the dietary being all important, and the medicine secondary only. Stated in a general way, the treatment should be directed towards controlling medically and supplementing surgically the automatic efforts of nature at resolution, not supplanting them. The symptoms of obstruction, if they are carefully analysed, enable us to use means which give the patient the best chance of escape

Digitized by Google

from his difficulty. During the early period of obstruction he suffers principally from pain, thirst, vomiting, and loss of appetite. Then let the pain be neutralised, which must extend the patient's period of endurance of the disease. Thirst must be satisfied, and the liquid, if containing no ingesta, is of service in helping to remove the matter loading the bowels above the obstruction. The means used to allay the vomiting will allow the fluid to be retained long enough to mix with the regurgitated fæcal matter, and so assist in its expulsion by the mouth. The loss of appetite is accepted, and no food is offered; but should the appetite return ere our purpose has been secured, then the quality of the nutriment must be selected. Manipulation should under no circumstances be attempted. Concerning operative measures, it was his opinion that to operate for diagnostic purposes was only to endanger the many and perchance save the few. These cases belonged to the department of medicine, the surgeon was a mere assistant. The period for operation was when the physician observed that his remedies failed to beneficially influence the complaint all round. For instance, though pain might be lessened, vomiting moderated, temperature lowered, yet should the tongue appear brown and dry, and the pulse, despite the sedatives, decrease in volume although reduced in rate, then the surgeon ought to be requisitioned. In deciding when to operate, it was not a question of period, but a question of signs that should influence our decision to operate or not. An operation may be required in a few hours or it may not be required for weeks. If the Sydenham method was adhered to from the beginning of the illness, urgent signs never appeared before the third day. Cases in which the signs of obstruction were due to a sudden invasion of the peritoneal cavity of a septic fluid were exceptions to the foregoing rule; but even then, if the leakage were slow, they did not show early signs of urgency. The medical treatment of the past, which was mostly mechanical, ought to be credited with much of the ill success of operative measures for the relief of obstruction. Better medical treatment would be an advantage in place of hindrance to successful surgery. He considered that it was most difficult to arrive at a correct differential diagnosis; but this was of very little importance to the surgeon, and of still less to the physician.

Dr. CARTER thought it necessary to remember that Mr. Durham, whose statistics Dr. Greves had quoted, made on these statistics two most important observations—viz.: (1) That they did not represent the true proportion of mortality, as gentlemen were so much more ready to publish their successful than their unsuccessful cases; and (2) that though in nearly every one of the fatal cases the operation as such was successful and the obstruction overcome, yet the patient sank. From this he (Dr. Carter) thought that any anticipation of success based on Dr. Greves' single case would be unfounded, and that probably the next case, even though in every particular similar, would have a different end. Having looked over his own hospital post-mortem records he could only find one case where it was in the least likely that abdominal section could possibly have done good; while in several others, which he briefly sketched, it would certainly have hastened the inevitable death. The great difficulties were to determine the situation and the nature of the lesion, and whether it was simple or multiple. He deprecated strongly the use of enemata, illustrating their harmfulness from a hospital case which had occurred in 1877. He considered that rest, position (such as raising the end of the bed so as to diminish the pressure of the liver on the intestines), opium, a very restricted fluid diet, and warm applications to the abdomen should be first tried, but that if, notwithstanding these, the symptoms became more grave, abdominal section should be performed, provided that, after consultation, it was thought likely to give the patient a chance of life.

Dr. CATON remarked that so far as his experience extended, a majority of the cases of obstruction recovered, if kept quietly in bed, on a limited diet, under the influence of belladonna and opium; a minority, however, die under this treatment. He had had one case in which the autopsy showed that an operation might have saved life. The great difficulty is to know when to rely on the expectant and when to have recourse to the operative method of treatment. Diagnosis is made rather easier if a resistant solid body be discoverable in the abdomen. This may be a mass of impacted fæces, or a tumour, or an abscess, or a gall-stone, or other foreign body in the intestine, or it may be an intussusception. A consideration of the history, position, and characters of such solid mass will generally give much aid in determining its nature, and probably in none of these cases would operative interference be desirable unless, perhaps, in that of intussusception. On the other hand, there may be no solid body discoverable, or the abdominal cavity may be so distended with flatus that, if present, it is masked. The cause may in this case be one of the above-named conditions, but it is more likely to be strangulation, by the passage of a loop of intestine through a hole in the mesentery or omentum, or its capture by a band of lymph, or by a diverticulum, or by the vermiform appendix, with its free end tied down by adhesion; or it may be one of the forms of internal hernia. Under these circumstances the question is, Can the case wait? If the symptoms are urgent, with quick pulse, great pain and distress, and if the patient be young and healthy, it may probably be wise to open the abdominal cavity. But if it be possible to allay the symptoms by moderate doses of belladonna and opium, and thus to restore comparative quiet and comfort, more particularly when the patient is neither young nor vigorous, it is better to rely on these measures and to wait.

Dr. DAVIDSON said that while Dr. Greves' case was a very successful one, it was exceptional, and did not in his opinion justify the operation as a general rule. He was aware that some surgeons held that abdominal section should be the rule of treatment in cases of acute intestinal obstruction, notwithstanding the terrible mortality which had resulted from the operation according to past experience. They said that the previous mortality arose from the operation being resorted to too late; and they argued, moreover, that modern antiseptic surgery had made operations on the abdomen much more successful than in past times. He would reply that the successful abdominal surgery referred to was mainly for removal of the uterine appendages, and that the injury and exposure of the intestines in ovariotomy, and the consequent danger of peritonitis and septicæmia, were much less than where the intestines had to be tumbled about, and handled and examined in searching for the seat of an obstruction. Moreover, in ovariotomy the patient was carefully prepared for the operation, whereas the operation for intestinal obstruction had to be done when the patient, owing to the protracted constipation, was already affected by the absorption of poisonous material from the retained contents of the bowel. The two cases were not analogous, and the success obtained in ovariotomy could not be hoped for in intestinal obstruction. As to the propriety of operating early, he did not see how early abdominal section could be made the rule of treatment in most cases of acute intestinal obstruction, seeing the diagnosis of the cause of obstruction was so difficult and uncertain. Moreover, even the most unpromising cases not unfrequently ended in natural recovery.

(To be continued.)

THE PROGRESS OF CHOLERA.

IF we accept the official notifications issued as to cholera in Paris, the epidemic must be looked upon as over; but since the returns last issued showed that as many as 221 patients were still under treatment on the 23rd ult., the complete disappearance of the disease must be regarded as having been exceptionally rapid. Up to the same date there had been 900 fatal cases, 14 having occurred on the last day of the period referred to. But even if cholera does still linger anywhere in France, the cases are probably but few and far between, and it is to be hoped that no recurrence of the epidemic may now take place. Italy, too, may be regarded as free from cholera, unless indeed the rumour of a fresh outbreak in Treviglio and near Turin be true; and as a consequence the political aspects of the disease and of quarantine are once more in the ascendant. It is with reference to this, and to the tenacity with which Italy clings to the notion of establishing a special quarantine system in connexion with traffic through the Suez Canal, that a proposal is being made to erect a lazaretto at Brindisi at a cost of 7,000,000 lire. One thing, however, is tolerably certain—namely, that if passengers from India found that by the Brindisi route they were subjected to quarantine and all its vexations, the route would be forthwith altered, and Brindisi with its lazaretto would for the time be carefully avoided. Except in so far as

Digitized by Google

Naples is concerned, there is as yet no detailed information as to a far more important expenditure of money—namely, in connexion with the removal of the conditions of filth, which in Spezzia and in other places enabled cholera to cling with such tenacity to the places it attacked. In Naples it is proposed to spend 100,000,000 lire, the expenditure to be spread over a period of twelve years.

Cholera still lingers in Toledo and Beniopa; there has also been a recent increase in Algeria.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Newcastle-upon-Tyne Urban District—Mr. Armstrong's reports on the health of this important city are always interesting, as showing that a large amount of sanitary work is steadily in progress year by year. In 1883 the birth and the death rates per 1000 living were 36·7 and 25·4 respectively. Under the system of compulsory notification of infectious diseases 2032 such cases were reported, these including 493 cases of small-pox, 90 of typhus, 216 of enteric fever, and 1152 of scarlet fever. The fact that so large a number of cases was brought under official cognisance gave a completeness to the inquiries as to infectious disease occurrence which had heretofore not been possible, even in a district where the investigations as to zymotic diseases had been exceptionally well conducted. Three hundred and eighty-four of the sick were removed to hospital, but the existing accommodation is not such as to meet the present requirements; two convalescents have contracted a second disease for lack of adequate isolation, and a new hospital is about to be erected. The authorities are also desirous to facilitate the isolation of paupers, and hence, in consideration of an annual allowance, they propose to receive all such cases free of extra charge. As many as 2045 cases of infectious disease have been inquired into with a view to disinfection, &c., a Washington Lyon's steam disinfector has been provided in addition to the Ransom's hot-air stove, and a large amount of disinfection and cleansing has been carried out. The dairies have received special attention; and owing to early notification four outbreaks of infectious disease in dairies came under notice, the necessary precautions were taken, and in no case did any spread of disease result. A very complete report has also been issued by Mr. W. George Laws, the city engineer, and Mr. Armstrong on the water-supply of the district. It commences with a history of the supply; it then enters into the principles which govern questions of water-supply generally, and goes on to describe in detail the existing works of the Newcastle and Gateshead Water Company. Mr. Laws arrives at the conclusions that the gathering-ground is a fairly good one, that certain reservoirs and aqueducts require additional protection from contamination, and that the increasing consumption makes it clear that an extension of gathering ground must take place. He also makes a few additional suggestions. Mr. Armstrong then deals with the subject from the point of view of health, and it is clear that he considers that the precautions at present taken to secure a water which shall be above all risk of contamination are not sufficient. He especially presses that conditions of drought are no excuse for an insufficient supply, and he recommends that the drought to be provided against should be one equal to only eighteen inches of rainfall per annum, such as occurred in 1850.

Southwell Rural District.—This rural district had a death-rate of 17·1 per 1000 in 1883; the zymotic rate being the lowest on record—namely, 0·6 per 1000. Five deaths occurred from fever, and in the old town of Southwell the presence of typhoid was found to be associated with the pollution of well-water by privy vault soakage. The report gives interesting information as to the principles which should govern sanitary work, and Mr. Wills supplies certain details as to action which has been taken.

Berkshire Combined Districts.—Dr. Woodforde's report on the sanitary condition of these combined districts is contained in one volume, and it is a record showing that careful supervision is maintained, and that steady progress is going on both as regards the construction of important sanitary works and the prevention of nuisances injurious to health. In the Abingdon urban district the population fail to avail themselves, as they should do, of the water-supply which has been laid on, still adhering to the use of wells sunk in the surface soil of the low-lying and ancient site on which so much of the borough stands. A wholesome supply, as also a sufficient supply for flushing, is thus wanting. Wherever the authority can do so—and in Abingdon not much difficulty should be experienced—they should insist on the use of the public service. Wallingford is also deriving its water largely from polluted wells, but some action has now been decided on. In other districts improved systems of scavenging and such matters are needed, but looking on the area as a whole it is evident that a vast amount of work has been carried out since Dr. Woodforde was first appointed, and also that further excellent measures tending to promote health are either in actual progress or in immediate prospect.

Ulverston Urban District.—Dr. Thompson reports a birth- and death-rate of 39·7 and 21·4 respectively per 1000 living. In connexion with certain fatal cases of enteric fever and diphtheria, it was found that the persons attacked with both diseases derived their milk from a common source, and it is pointed out that both diseases had simultaneously one common cause—namely, an infected milk-supply. It has often been suggested that enteric fever and diphtheria have much in common as regards causation, but we are not aware of any case in which it has been distinctly shown that a polluted milk was capable at one and the same time of producing both diseases. We could have wished, in view of the importance of the subject, that the histories of the cases had been given in much greater detail in so far as their etiology is concerned, and that proof had been adduced as to the exclusion of all other sources of infection. As to the cause of the enteric fever there is not much doubt, since that disease prevailed in the dairy farm, but with the diphtheria it is different.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5680 births and 3994 deaths were registered during the week ending the 29th ult. The annual death-rate in these towns, which had been equal to 20·9 per 1000 in each of the two preceding weeks, rose last week to 23·8, and exceeded the rate recorded in any week since the beginning of September. During the first eight weeks of the current quarter the death-rate in these towns averaged 21·1 per 1000, against 21·7 and 21·0 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 17·3 in Plymouth, 18·5 in Derby, 19·1 in Sheffield, and 19·4 in Brighton. The rates in the other towns ranged upwards to 28·7 in Manchester, 30·2 in Nottingham, 30·7 in Cardiff, and 31·6 in Bolton. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 369 and 391 in the two previous weeks, rose to 395 last week; these included 83 from measles, 76 from scarlet fever, 73 from whooping-cough, 53 from "fever" (principally enteric), 39 from diarrhœa, 37 from diphtheria, and 34 from small-pox. These zymotic diseases caused the lowest death-rates in Portsmouth, Plymouth, and Bristol; and the highest in Leeds, Preston, and Cardiff. The greatest mortality from measles was recorded last week in Bolton, Hull, and Cardiff; from scarlet fever in Leeds, Sheffield, and Salford; from whooping-cough in Oldham, Wolverhampton, and Preston; and from "fever" in Derby, Halifax, and Leeds. The 37 deaths from diphtheria in the twenty-eight towns included 16 in London, 6 in Liverpool, 3 in Nottingham, 3 in Cardiff, and 2 both in Birmingham and Leeds. Small-pox caused 50 deaths in London and its outer ring of suburban districts, 2 in Birkenhead, and 1 both in Leeds and in Cardiff. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had increased from 580 to 768 in the three preceding weeks, had further risen to 884 on Saturday last; the new cases admitted, which had been 233, 200, and 149 in the three previous weeks, rose again to 228 last week. The Highgate Small-pox Hospital contained 58 patients on Saturday last, 24 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 370 and 354 in the two preceding weeks, rose to 511 last week, and exceeded

Digitized by Google

the corrected weekly average by 6. The causes of 108, or 2·7 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Newcastle-upon-Tyne, and in five smaller towns. The largest proportions of uncertified deaths were registered in Hull, Oldham, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 22·3 and 26·2 per 1000 in the two preceding weeks, further rose to 28·6 in the week ending the 29th ult., and was 4·8 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 18·5 and 22·2 in Edinburgh and Greenock, to 31·9 in Perth, 32·1 in Paisley, and 36·9 in Glasgow. The 689 deaths in the eight towns included 30 which were referred to measles, 21 to diphtheria, 19 to whooping-cough, 14 to scarlet fever, 14 to diarrhœal diseases, 3 to "fever," and not one to small-pox; in all, 101 deaths resulted from these principal zymotic diseases, against 103 and 115 in the two preceding weeks. These 101 deaths were equal to an annual rate of 4·2 per 1000, which exceeded by 1·8 the rate from the same diseases in the twenty-eight English towns. The 30 fatal cases of measles, of which 21 occurred in Glasgow and 6 in Aberdeen, were fewer by 4 than the number in the previous week. The 21 deaths from diphtheria corresponded with the number in the previous week, and included 3 in Edinburgh, 3 in Leith, and 10 in Glasgow. The fatal cases of whooping-cough, which had been 16 and 27 in the two previous weeks, declined again to 19 last week, of which 12 occurred in Glasgow. Nine of the 14 deaths from scarlet fever, corresponding with the number in the previous week, were returned in Glasgow. Of the 14 deaths attributed to diarrhœal diseases, 5 occurred in Glasgow and 5 in Dundee. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 101 and 145 in the two previous weeks, further rose to 181 last week, and exceeded by 52 the number returned in the corresponding week of last year. The causes of 91, or more than 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had increased from 24·7 to 32·7 per 1000 in the four preceding weeks, further rose to 35·4 in the week ending the 29th ult., and exceeded the rate returned in any previous week of this year. During the first nine weeks of this quarter the death-rate in the city averaged 28·9 per 1000; the rate during the same period did not exceed 19·4 in London and 19·0 in Edinburgh. The 238 deaths in Dublin last week showed a further increase of 18 upon the numbers returned in recent weeks, and included 23 which were referred to the principal zymotic diseases, against 18, 25, and 39 in the three preceding weeks; 11 resulted from scarlet fever, 5 from diarrhœa, 4 from whooping-cough, 2 from "fever" (typhus, enteric, or simple), 1 from measles, and not one either from small-pox or diphtheria. These 23 deaths were equal to an annual rate of 3·4 per 1000, the rate from the same diseases being 1·9 both in London and in Edinburgh. The fatal cases of scarlet fever in Dublin, which had been 8, 10, and 16 in the three preceding weeks, declined to 11 last week. The deaths referred to "fever," whooping-cough, and diarrhœa also showed a decline. Four inquest cases and 6 deaths from violence were registered last week, and 82 deaths were recorded in public institutions, a higher number than in any previous week of this year. The deaths both of infants and of elderly persons showed an increase upon those in the previous week. The causes of 32, or more than 13 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Deputy Surgeon-General Archibald Henry Fraser to be Surgeon-General, vice Alexander Smith, M.D., C.B., granted retired pay; Deputy Surgeon-General Herbert Taylor Reade, V.C., from half-pay, to be Deputy Surgeon-General, vice Archibald Henry Fraser, promoted; Deputy Surgeon-General John Hendley, C.B., to be Surgeon-General, vice Jones Lamprey, M.B., granted retired pay; Brigade Surgeon Stewart Aaron Lithgow, M.D., to be Deputy Surgeon-General, vice John Hendley, C.B., promoted; Brigade Surgeon William Skeen, M.D., to be Deputy Surgeon-General, vice Leonard Kidd, M.B., deceased; Surgeon Richard Henry Stewart Sawyer, M.B., has been placed on temporary half-pay, on account of ill-health.

INDIA OFFICE.—The Queen has approved of the transfer of Surgeon Francis Joseph Tuohy, M.D., of the Bengal Medical Establishment, to the half-pay list.

ADMIRALTY.—Fleet Surgeon William Harris Lloyd, M.D., has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet.

The following appointments have been made:—Surgeon William H. Norman, to the *Reindeer*; Augustus W. Dalby to be Surgeon and Agent at Torquay and Babbicombe; Julius Cæsar to be Surgeon and Agent at Scrapegate, East-end-lane, Leysdown, and Shellness.

Correspondence.

"Audi alteram partem."

COCAINE.

To the Editor of THE LANCET.

SIR,—Cocaine as a local anæsthetic is at present attracting the attention of the profession. I venture to make a few observations on the subject, having been, as far as I am aware, the first in this country to extract this alkaloid from coca, and to investigate its physiological properties. In 1872 coca leaves were almost unknown in England except as botanical curiosities, and it was with great difficulty and at considerable expense that I obtained from Paris a couple of pounds of their concentrated extract. From this the celebrated chemists, Messrs. Macfarlan and Co., of Edinburgh, obtained at my request a few grains of cocaine. In the autumn of that year I presented a thesis to the University of Edinburgh entitled "Erythroxylon Coca," in which the physiological properties of coca and its alkaloid cocaine were fully investigated, and the conclusions detailed of an elaborate inquiry, the result of a series of experiments and observations conducted on a large number of living animals. An abstract of this research appeared in the *Edinburgh Medical Journal* of October, 1873, to which I refer those interested in the matter.

My object in now addressing you is to point out that the practical use to which cocaine has recently been put as a local anæsthetic completely harmonises with the physiological conclusions at which I arrived twelve years ago. The general result of the inquiry then conducted was to show that this substance when injected under the skin was a powerful poison, inducing a varied series of symptoms affecting the nervous, respiratory, circulatory, vaso-motor, and glandular systems. Without here entering into all the phenomena observed, it may be interesting, in connexion with the present practical application of the drug, to note the effects on the nervous system then determined. These shortly summed up are as follows:—1st. In small doses not ending fatally, cocaine causes partial general loss of sensibility. 2nd. In doses which are subsequently fatal, it induces, prior to death, complete general loss of sensibility. 3rd. It destroys the excitability of the posterior columns of the cord, and paralyses the entire system of peripheral sensory nerves; but the anterior columns and the peripheral motor nerves remain intact. 4th. It causes spontaneous convulsions; but, unlike those induced by strychnia, they are not excited by peripheral irritation, owing to the paralysis of the sensory nerves. 5th. Special experiments proved that the nerve endings in the skin and mucous membranes were rendered inexcitable apart from any action the drug had upon the nervous centres.

Thus physiological experiment has already demonstrated the local and general anæsthetic effects of cocaine. Although the present method of its application in practice had not then suggested itself, I at the time ventured to predict that the varied and potent properties of this substance would subsequently "prove a powerful and valuable agent in the hands of the physician for the treatment of disease."

In connexion with the local anæsthetic effects of cocaine

Digitized by Google

which are at present occupying the attention of surgeons, there are certain facts which may possibly prove of practical value. While conducting my experiments with this substance, which is the active principle of the national beverage of Peru, I also turned my attention to the alkaloids of other popular drinks, such as tea, coffee, chocolate, and guarana. It had been before determined that theine, caffeine, theobromine, and guaranine were almost identical in chemical composition, and also somewhat allied to cocaine. By actual experiment I demonstrated that the physiological properties of all these substances when administered hypodermically were to all appearances the same. Should it be proved that they have also similar effects when applied externally to the mucous membranes, it would be of importance from an economic point of view, as cocaine is extremely expensive, while the others are comparatively cheap. I have myself no experience on this special point, but only offer as a suggestion that theine or caffeine should be tried for the same purposes for which cocaine has been found efficacious. The chief objection to their use will consist in the very sparing solubility of both, but this difficulty could doubtless be overcome. I am, Sir, yours truly,

Queen Anne-street, W., Nov. 30th, 1884. A. HUGHES BENNETT.

To the Editor of THE LANCET.

SIR,—I desire to add my testimony to the extreme value of the muriate of cocaine as a local anæsthetic in cases of operation upon the eye. I have now used it in a large number of cases, and if I state what, in my opinion, it can and cannot do, it may prevent disappointment in others who by exaggerated reports may have been led to expect too much from this drug.

First, I will state my own personal experience of a 4 per cent. solution as applied to my own conjunctiva. The first contact of the solution is rather painful, much the same as though a drop of weak spirit were placed in the eye. This, however, soon subsides, and is succeeded by a sensation of weight and dryness of the conjunctiva. At the end of five minutes the pupil begins slightly to dilate, and the conjunctiva becomes to a certain extent anæsthetic. If now another drop of the solution is added, in a few moments all the symptoms become materially intensified. There is a decided sensation of weight and numbness about the eye if the two eyes are exposed to a strong current of air, as by blowing upon them, or otherwise the sensation is not felt upon the anæsthetic side, and there is a feeling of vacancy if the globe is rubbed with the hand. At the end of twelve minutes my conjunctiva was perfectly anæsthetic. I could touch the cornea with a pointed instrument, and seize the conjunctiva with fixation forceps without experiencing any sensation. The pupil was midway between contraction and dilatation, but the accommodation was unaffected. At the end of fifteen minutes I applied a third drop of the solution. The anæsthesia remained the same, but the pupil began to dilate rapidly and the near point to recede. In twenty-five minutes from the first application there was complete paralysis of the accommodation, but without the same amount of pupillary dilatation as atropine would produce; beyond this, however, there was a slight but decided amblyopia, $V = \frac{6}{9}$ (my refraction is normal). I placed no further solution in the eye, and in half an hour from the last application sensation had perfectly returned. It was three hours before the accommodation was restored. Some pupillary dilatation and amblyopia were present when I went to bed at 10 P.M. (I had commenced my experiments at 3 P.M.), but the eyes were normal in every respect in the morning. I think the course of events as described in my own person are very much like what takes place in other persons. Children, however, as one would expect, are much more susceptible to the drug than elderly persons, and frequently one application will produce anæsthesia in them.

Now, I think the anæsthetic properties of the drug should not be exaggerated; its effects are quite superficial. It does not extend beyond the conjunctiva and cornea, and therefore it will not give complete success in any operation involving other ocular structures; nevertheless it unquestionably mitigates the suffering in all operations on the globe. I have performed several cataract operations perfectly painlessly: tapped the cornea, removed a pterygium, cauterised ulcers, &c., without any evidence of pain or inconvenience beyond what is experienced by the introduction of the speculum. In iridectomy the pain of excising the iris is not diminished, and in tenotomy of the ocular muscles and excision of the globe the pain is but slightly numbed.

One word more before I conclude. Apart from the question of the use of this drug in operations, I think therapeutically it is destined to play an important part in ophthalmic practice. Its application is attended with marked benefit in all painful corneal affections, notably in those cases of phlyctenular ulceration and extreme photophobia, which are so common in strumous children, and have hitherto proved a bane to the ophthalmic practitioner.—Yours truly,

C. S. JEAFFRESON, F.R.C.S.Ed.,
Dec. 2nd, 1884. Surgeon to the Eye Infirmary, Newcastle-on-Tyne.

To the Editor of THE LANCET.

SIR,—It may interest your readers to know that under the local influence of cocaine I applied to the tongue this morning fuming nitric acid. The tongue was dried, drawn out, and the 20 per cent. solution was painted over a surface about the size of a shilling. This was repeated three times within the course of ten minutes. At the expiration of the ten minutes the acid was applied to nearly the same extent as the anæsthetic so as to produce a definite eschar. The acid was applied two or three times, and as freely as I should have done it under chloroform. The patient, a well-known member of our profession, assured me that he had no sensation of pain during or after the process. There was no physiological effect produced, except a complete local anæsthesia. I am, Sir, yours obediently,

Stratford-place, W., Dec. 4th, 1884. THOMAS SMITH.

To the Editor of THE LANCET.

SIR,—It may be of use to record the fact that during the past month I have, under the influence of both 2 and 4 per cent. solutions of cocaine, kindly sent me by Messrs. Allen and Hanburys, removed small polypi from the tympanum, and applied chloro-acetic acid to the granulations both on the membrane and in the tympanic cavity, without the least pain. I applied it by simply dipping my aural probe armed with cotton-wool into the solution, and applying the wool thus wet to the previously dried and cleansed surface. I have just now, to a most sensitive patient, applied chloro-acetic acid without the least pain following. I allowed over five minutes' interval to elapse between each application of the cocaine, and then ten minutes before I removed the polypus or applied the acid. I am, Sir, yours truly,

Harley-street, W., Nov. 30th, 1884. H. MACNAUGHTON JONES.

To the Editor of THE LANCET.

SIR,—May I be allowed to add my testimony to the value of cocaine as a local anæsthetic in ophthalmic operations.

Through the kindness of Mr. Jakins I was able to excise a globe at the Western Ophthalmic Hospital on Saturday last. The patient had previously undergone two iridectomies. Ether was administered on each of these occasions. On this occasion a few drops of a 2 per cent. solution of cocaine was instilled, and as soon as practicable after anæsthesia was produced the operation was commenced. The patient said he felt something while the tendon of the internal rectus was being hooked up and divided, and a few more drops were then instilled, and he made no more remarks until the operation was completed. When he was told the operation was over, he announced it to be his opinion, and I regard it in the light of the opinion of an expert, that "it [cocaine] was a great deal better than that beastly ether."

I remain, Sir, yours very truly,

T. W. CARMALT JONES,
Dec. 1884. Assistant-Surgeon, Western Ophthalmic Hospital.

THE CONVICT BRIGGS.

To the Editor of THE LANCET.

SIR,—The case of the man Briggs, to which Mr. Bond calls attention, is interesting both on account of the medical evidence and the verdict of the jury founded thereon. The symptoms and post-mortem appearances in his wife's case, relied upon as evidence of starvation, are not such as I should expect to find in a case of starvation; and as to the

Digitized by Google

convict himself, he is a feeble-minded, apparently harmless old man, who has not in the least the aspect of a criminal, while his physical defects would render him much more likely to be a victim than an aggressor. He has been treated at various London hospitals for disease of the eye, and when I saw him the pupil of the left eye was nearly closed, and the right eye so defective from large patches of retinal atrophy that he certainly could not, as he says, "see across the table whether his wife had any food on her plate or not." I have not seen the whole of the evidence in this case, but *a priori* I certainly do find it difficult to understand how a man like this could starve a woman to death who had property of her own and was free to come and go.

I am, Sir, your obedient servant,
CHARLES BELL TAYLOR, M.D., F.R.C.S.E.,
Surgeon to the Nottingham and Midland Eye Infirmary.

MANCHESTER.

(*From our own Correspondent.*)

VICTORIA UNIVERSITY.

WHILST the London medical schools are complaining of the difficulties which surround their students in obtaining a medical degree the provincial schools are on the highway to solve this difficulty in a satisfactory manner. As already reported in your columns, at the last meeting of the court of the Victoria University the Liverpool University College was admitted as a college in the university, and its students are now on the same footing as ours of Manchester in regard to facilities for graduating in the Victoria University, and it is highly probable that not a long period will elapse ere other colleges will come forward to claim admission also. In the brief report which was allowed to become public of the proceedings of the court it was stated that considerable discussion took place before the proposal, which was submitted by Lord Winmarleigh and seconded by the Bishop of Manchester, to admit Liverpool as a college in the university, was adopted. It would have been more satisfactory to the general public, and particularly to those interested specially in the matter, if more publicity had been given to this discussion, as to the nature and extent of any objections which were raised. In the meantime could not some of the London schools, such as King's College and University College, in the absence of more facilities granted them at the London University, also take steps to become affiliated to the Victoria University, and thus afford their students a reasonable chance of obtaining a medical degree without the necessity of leaving London to take out the required residence in Scotland or Ireland, where now so many Englishmen have to go if they wish to write M.D. after their name?

THE HOSPITAL SATURDAY AND SUNDAY FUND.

At the annual meeting recently held in connexion with the Hospital Saturday and Sunday Fund the total amount raised was reported to be £8442, being an increase of nearly £1000 on last year's collection; but this increase was due to two large legacies of £500 and £315 received towards the fund. The Sunday collections realised £5505 and the Saturday contributions £2937. During the fifteen years that the movement has been in existence no less a sum than £106,789 has been raised.

THE HOMES OF THE POOR.

A very modest but most useful work has for some time been going on in connexion with the improvement of the homes of the poorer classes. "The Manchester Cottages Committee," chiefly composed of ladies, is a voluntary association which has for some time quietly laboured with the above object in view. They have taken a small block of houses, and by direct personal intercourse and supervision with the dwellers therein, they are endeavouring to raise both their physical and moral condition. The hon. sec., Mrs. Roby, appealed for help recently—help not so much of a pecuniary as of a personal character—"for volunteers, ladies of energy and leisure in the vicinity of Manchester who would be willing to devote some two or three hours weekly to the work." She says, "the work is neither dangerous nor difficult, though sometimes disagreeable." Such a practical endeavour to solve the difficult question of the better housing and accommodating of the poor deserves support.

VEGETARIANISM.

Many visitors to the "Healtheries" who patronised the vegetarian restaurant, whether from choice or curiosity, will be unaware that the Society under whose auspices it was conducted hails from Manchester. At the thirty-seventh annual meeting recently held here some interesting details were given by the manager of the exhibition restaurant. It was stated that a grand total of 107,982 dinners were served and 41,731 teas, and that the receipts during the last week were £228. We have here, in active operation, a very large vegetarian restaurant which is doing an extensive business, and there was lately registered a vegetarian restaurant company "for the purpose of establishing refreshment houses in which neither fish, flesh, nor fowl, nor any combination thereof, will be sold"; wine, ale, spirituous liquors, and tobacco being also amongst the articles tabooed. It was registered with a capital of £20,000 in £1 shares.

THE MEDICAL STUDENTS' ANNUAL DINNER.

On November 6th the annual dinner of the medical students was held at the Grand Hotel, which certainly was not given on the lines of the above prospectus. Upwards of 100 sat down, the greater number being actual students at present attending classes, very few older ones or qualified men being present. As visitors, some students from Liverpool came to represent the medical school there, and were received in a very cordial manner. Until this year it has been the custom to hold two dinners, one (that now alluded to) for students proper; the other the "medical dinner," attended by older men and practitioners of the district, but for some reason or other the latter has this year fallen through. This is rather to be regretted, as it formed a pleasant annual reunion for men who a few years since were fellow students, but are now separated and settled in practice, and has always been well attended.

EXTENSION OF THE SALFORD ROYAL HOSPITAL.

At the annual meeting of the subscribers to the Salford Royal Hospital it was resolved to proceed at once with the extension of that institution at a cost of some £8000 or £9000. At present there is accommodation for only fifty patients; when the extension is completed, room will be provided for 100 beds, and the hospital will then fulfil the conditions for recognition as a clinical hospital for the instruction of students.

THE PRESENT STATE OF THE LAW RESPECTING CERTIFICATES IN LUNACY.

At the last meeting of the Medico-Ethical Society, held on Nov. 28th, there was a large attendance of members to hear a paper by Mr. G. Mould on this subject. In the course of his remarks he brought forward instances where medical men who, after complying in a legal manner with the requirements of the Lunacy Laws, had yet had actions brought against them on charges of conspiracy or libel, although the number of such cases, when compared with the total number of certificates given by medical men, was very small; and he suggested, in order to relieve medical men of even this comparatively slight risk, that when a patient was found to be insane, instead of being committed direct to an asylum on the medical certificates, the patient should be taken before a commissioner of oaths, and that he, after receiving the medical evidence, should commit the patient to the asylum. The discussion which followed was somewhat prolonged.

THE RECENT M.B. LOND. EXAMINATION.

The names of six Manchester students appear in the pass list of the recent M.B. Lond. Examination, four being in the first division, four of whom appear in the honours list; Mr. W. Thorburn, son of Dr. Thorburn, our lecturer at the college on obstetrics, standing first with the scholarship in medicine, Mr. J. Jones taking fourth place; whilst in obstetrics Mr. Thorburn is second with the medal. These results will be received with much satisfaction by all who take an interest in the progress of our local school of medicine.

ONE HUNDRED GUINEAS are offered as a prize for an essay on the Physical and Moral Advantages of Total Abstinence from Intoxicating Liquors. The competitors must be *bonâ-fide* medical students at some recognised medical school in the United Kingdom. Particulars may be obtained from J. J. Ridge, Hon. Sec. of the British Medical Temperance Association, Carlton House, Enfield.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE.

NOTICE has been served by the North-Eastern Railway directorate on the officials of the College of Medicine stating the company's intention, under its Parliamentary powers, to apply for the purchase of the College buildings for the purpose of the extension and improvement of the Central Railway station. It is supposed that, owing to the delay of the railway company in serving this formal notice, the College authorities have, up to this, been reluctant to take any active steps in providing a new building, so that we may now hope to see one erected at once suitable for its purpose, and an architectural feature in the city. The returns of practitioners notified to the medical officer of health show an increase in scarlet fever, no fewer than 115 cases having occurred in the last fortnight. The Newcastle Infirmary is at present sadly overcrowded. Last week the number in the house was 259, while the building only properly accommodates 219 patients.

A CURIOUS MINERS' CASE.

The members of the Northumberland and Durham Miners' Permanent Relief Fund have had before them a very curious and troublesome case, in which the difference of opinion has not been altogether on the medical side. The "Philadelphia" case (so it is called) had its origin in this way: A member of the fund was hurt by a fall of stone, but worked on until his shift was over. His injury then compelled him to be off for a few days; he afterwards returned to his work, but finally was laid up once more on what proved to be his death-bed. Then came the question, Did the man die of typhoid fever from which he was alleged to have suffered, or from the injuries which were caused by the accident? This was a serious question for the widow. In the former case she would be entitled to an allowance from the Permanent Fund, and in the latter case she would have no claim upon it. The medical evidence, although not altogether free from conflict, supported very strongly the view that the fever was at all events the cause of death. It was held on the other side that, although the fever was undoubtedly the immediate cause of death, it might be looked upon as the remote or finishing stroke of the accident, and that the patient might have fought typhoid successfully had he not been already weakened by the effects of the accident. The matter has been very warmly taken up and debated, and handed on from lodge to lodge, and there has been a disposition to err, if at all, on the generous side, provided the rules of the fund interposed no legal bar. The Washington Lodge advised that the widow should abandon the enforcement of the claim, and throw herself on the generosity of the members, leaving them to do their best for her, and this on all sides appears to be the best way of solving this curious and difficult case.

SERIOUS OUTBREAK OF SCARLATINA AT WOMBWELL, YORKS.

At the last meeting of the Wombwell Local Board, Dr. Millar, medical officer of health, presented an important report relating to the outbreak of scarlet fever of a serious type. He said about the middle of last month the disease seemed to abate, and for eight or ten days no new cases occurred; within the previous four days the severity of the attack had become greater, not so much from the numbers attacked giving anxiety, as from the rapidity with which a fatal result ensued, death often taking place within twelve hours and before medical aid could be of any avail. The number of cases, so far as he could gather, since the beginning was about 200, of which 37, or 18 per cent., had proved fatal. During the month ending Nov. 22nd there had been 33 deaths. The births registered during the month had been 30, and this was the first time he had known the birth-rate to have been below the death-rate. Everything had been done to check the disease, and he hoped the frost and cold weather would further diminish it.

THE LATE FATAL ACCIDENT FROM ELECTRICITY.

As to the accident at Messrs. Bolkow, Vaughan, and Co.'s, where a workman lost his life from touching the connexions, an inquest has been held, and Dr. Glen, who had been called in, deposed that death had been instantaneous, the body presenting all the appearances of a death from lightning. The hands were dreadfully scorched, as if the contact had been with hot iron. It was not a part of deceased's duty to interfere with the lights. The recklessness of workmen is sometimes astounding. A miner the other day was brought up before the magistrates and fined for drilling a hole in which there was a pound of gunpowder. The bit of course was steel, and a spark would have annihilated him and his companions. Worse than this almost, he shortened the regulation fuse, and not finding the charge exploding, he went near, to see "how it was getting on."

Newcastle-on-Tyne, Dec. 3rd.

PARIS.

(From our Paris Correspondent.)

THE CASE OF M. MORIN.

M. MORIN, the victim of the tragic scene that took place on Thursday last at the Palais de Justice, after having been shot by Madame Clovis Hugnes for slander, as reported by the daily papers, was immediately removed to the Hôtel Dieu in a very dangerous condition, owing to profuse hæmorrhage. Three bullet wounds were discovered on the patient; one on the back at the inferior angle of the left shoulder blade, the second in the right side of the neck, and the third at the top of the head; all were caused by bullets fired from a six-barrelled revolver. The wound in the neck was considered the most serious. The bullet entered on the right side about the level of the thyroid cartilage, and, wounding the larynx, lodged above the left clavicle, where it is distinctly felt, but which the surgeon (Dr. Peyrot) did not consider it urgent to remove, though there was some amount of emphysema in the parts. A second bullet entered the skull about eight centimetres above the left ear, the opening measuring about five millimetres. About three or four centimetres from this, on the top of the skull, was found another wound, and as the right hand of the patient was paralysed it was presumed that the brain, in the region indicated above, must have been wounded. At the visit next morning (Friday), Dr. Peyrot probed the wounds in the skull, and discovered a slight depression of the bone, which was evidently the track of the bullet, which he supposed must have escaped through the other opening. The patient was conscious the whole time. On Saturday morning he became unconscious, and was somewhat feverish; the paralysis of the right hand extended up the arm, which led the surgeon to suppose that there was deep-seated mischief going on in the brain, due to the depression of the fractured portion of the skull. He therefore decided upon trephining that part of the skull. The operation lasted about an hour, and was performed under chloroform, and on strict Listerian principles. An opening of two centimetres and a half was made through the skull in the site of the wound, and a fragment of bone of about the size of a half-crown piece was removed. The wound was then thoroughly explored, and the membranes were found to be intact. The wound was properly dressed, and the operation was thought to be entirely successful. A small artery, however, soon began to bleed, and gave trouble for fully half an hour. It then became a question whether the opening in the skull should not be enlarged, in order to arrest the flow of blood. The hæmorrhage, however, was finally stopped with pieces of cotton steeped in a hæmostatic fluid called "eau hémostatique de Pagliari," which is composed of alum, benzoin, and water. The operation was attended with some relief to the symptoms of compression of the brain, but on Sunday evening last those of encephalitis were observed, marked by a pulse of 118 or 120, temperature 39° to 40° C. The patient was restless, and the respiration irregular; both eyes inclined to the left, and were of a somewhat yellowish tint; urgent thirst. Consciousness was apparently preserved, but the patient was unable to answer questions put to him. The bullet which was lodged below the left shoulder blade was extracted at the same time that the trephining was performed. I am indebted for these details to my friend Dr. Nachtel, who witnessed the operation and followed the case from the beginning. Yesterday morning Dr. Peyrot, in redressing the wound, observed that the dura mater was rather tense, and slightly incised it to relieve the pressure on the brain. At the surgeon's visit at seven in the evening a change for the

Digitized by Google

better was observed. The temperature went down by nearly 1 degree, the pulse was 100, and the expression of countenance of the patient was rather better; his strength is kept up with milk-and-brandy. Although there is some improvement in the condition of the patient, yet Dr. Peyrot is rather reserved in his prognosis. M. Morin seems conscious, but he is unable to utter a word, owing, as is supposed, to the bullet having wounded in its passage through the skull that part of the brain contiguous to the convolution which is looked upon as the seat of the faculty of speech.

Paris, Dec. 3rd.

MEDICAL NOTES IN PARLIAMENT.

Compulsory Vaccination.

IN the House of Commons on Monday, Dec. 1st, Mr. G. Russell, in reply to a question by Mr. Hopwood, stated that he was not prepared to assent to the view that because one child may have suffered owing to *malapraxis* or some accidental circumstance, all the other children should be deprived of the protection which vaccination affords. At the same time it was open to the justices in any such case to impose a nominal fine, or decline to make an order for the vaccination of the child, and he should hope that if any such case occurred it would be considerately and tenderly dealt with.

The Natural History Museum.

Mr. Shaw-Lefevre, replying to Sir H. Verney, stated that already fourteen acres of land had been secured for the extension of the Natural History Museum at Kensington, and this amount was considered quite sufficient. It was not, therefore, proposed to attempt to secure the grounds lately occupied by the Health Exhibition for the purpose.

Captain of Orderlies C. Cook.

On Thursday, replying to Mr. Justin M'Carthy, Sir A. Hayter, said that Captain of Orderlies C. Cook, "late" Army Hospital Corps, exercised the same command in the Medical Staff Corps that he exercised in the Army Hospital Corps. He has the pay assigned to his rank by former Royal Warrant, which Warrant did not provide for an increase of such pay; but it is open to him to accept the terms first offered in 1881, in which case he would attain the same rates of pay as the other officers who are his contemporaries as Captains of Orderlies, and who have accepted the new terms.

MEDICAL TRIALS.

PRINCIPALS AND ASSISTANTS.

SHARMAN AND OTHERS *v.* GILLIES.

THIS was an action tried before Mr. Justice Wills last week. It was brought by Messrs. Sharman, Harris, and Clark, medical practitioners of Lower Norwood, to restrain the defendant from practising within four miles of Oak-villas, Lower Norwood. Mr. Hugh Cameron Gillies, in March, 1883, made an agreement to act as assistant to the firm, the agreement being terminable at three months' notice, and by it the defendant agreed that on leaving the employment of the plaintiffs he would not practise within four miles of Oak-villas. In November, 1883, for certain reasons the plaintiffs became desirous of terminating the agreement, and on Nov. 29th, they gave the defendant three months' notice to leave them. It was, however, arranged that the defendant should leave at the end of two months, and the defendant accordingly left on January 29th, 1884, the plaintiffs paying him a month's salary on account of his leaving one month before the expiration of the notice. Upon his leaving the plaintiffs the defendant commenced practising at Zingari-terrace, which is near Oak-villas, having his name over the door. The plaintiffs commenced their action against him, and on February 8th he removed his name from the house, and ceased to practise on his own account. On February 11th the name of Dr. Hulleseburgh, of Maidstone, was put up at the house at Zingari-terrace occupied by the defendant, and the defendant's case was that he had on that day made an agreement with Dr. Hulleseburgh, who had in 1882 commenced to practise at Avenue-gate, Gipsy-hill, to act as his assistant. The agreement was not forthcoming, his solicitor, Mr. Wrightson, having lost it. The defendant declared that his line of conduct had been backed up by the junior member of the firm, Dr. G. B. Clark, who was then contemplating leaving the partnership. One clause of the agreement states that the defendant should practise at Norwood as the plaintiffs' assistant, and in another clause that the defendant on leaving the service of the firm should not practise within four miles of Oak-villas. The defendant submitted that he was not practising within the meaning of the last clause. His Lordship, referring to the evidence which had been given, and particularly to the facts that Dr. Hulleseburgh had left the neighbourhood in June and was now living at Maidstone, that there had not been any settlement of accounts, that drugs had been bought in the name of the defendant, that not more than seven of the patients in defendant's books out of 105 had been patients of Dr. Hulleseburgh, and that the house at Zingari-terrace was close to the plaintiffs' house at Oak-villas, but half or three-quarters of a mile from Dr. Hulleseburgh's, was of opinion that the agreement with Dr. Hulleseburgh was a merely colourable arrangement intended to enable the defendant to evade his agreement with the plaintiffs. If this had not been so, his opinion would still have been, having regard to the circumstance that Dr. Hulleseburgh was not himself practising at Lower Norwood, that the defendant was practising within the meaning of his agreement with the plaintiffs.

His Lordship granted an injunction with costs, leaving the question of damage sustained by the plaintiffs to be determined by the official referee of the Court. Mr. Finlay, Q.C., and Mr. Peile appeared for the plaintiffs, Mr. Terrell and Mr. Ghosh for the defendant.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 1st inst.:—

Gray, Thos. U., L.R.C.P. Lond., Essex-road, St. Barth. Hosp.
Mullis, George H., L.S.A., Northampton, Guy's Hospital.
Dickinson, J. J., L.S.A., Bow-road, London Hospital.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following have passed the first half of their examination for the diploma in Surgery of the College:—

Robert J. Adamson, Jeremiah Behan, Hugh A. L. Brenan, Charles Casey, Edward J. Good, Joseph W. Gallagher, Guy S. L'Estrange, William A. Mahon, James J. McGrath, Joseph C McFeely, Thomas J. O'Reilly, William Peacock, William J. Russell, William G. Toomey, James G. Westlake, Benjamin P. Young, Charles A. Young.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Nov. 27th:—

Childe, Charles Plumley, King's College.
Dutt, Upendra Krishna, St. Mary's Hospital.
Jolliffe, Albert Robert, Charing-cross Hospital.
Ladell, Mordaunt Percy, London Hospital.
Quartley, Selwyn Warner, Middlesex Hospital.
Reed, Henry Albert, Guy's Hospital.
Steer, Adam Wm. Thorburn, St. Bartholomew's Hospital.
Taylor, Charles Henry, King's College.

The following gentleman also on the same day passed the Primary Professional Examination:—

Gaerett, John Henry, University College.

THE Miller Memorial Hospital at Greenwich is to be opened for the reception of patients on the 17th inst.

ROYAL INSTITUTION OF GREAT BRITAIN.—Drs. George Mann Carfrae and James P. Harper have been elected members of the Royal Institution.

THE salary of Mr. A. Wynter Blyth, medical officer of health and analyst for Marylebone, has been increased from £400 to £500 per annum.

GEORGE PLUNKETT O'FARRELL, A.M., M.D., of Tangier Boyle, has been placed on the Commission of the Peace for the County Roscommon.

MOTHERS' LYING-IN HOSPITAL.—Mrs. Gladstone is to open the above home, situated in Juniper-street, Shadwell, E., to-day (Saturday), at 11.30 A.M.

THE Assembly of New York has passed a Bill prohibiting the sale of drugs by any persons except physicians and pharmacists. The grocers are indignant.

ROYAL SOCIETY. — Professor Huxley has been elected President of the Society for the ensuing year, John Evans, D.C.L., LL.D., Treasurer, and Professors G. G. Stokes and Michael Foster, Secretaries.

ON the 28th ult. an inquest was held at the London Hospital on the body of a man who died during the administration of ether previous to an operation for stricture. The jury returned a verdict in accordance with the medical evidence.

THE Twickenham Local Board have resolved to ask the Local Government Board to receive a deputation to set forth the bad condition of the Thames above bridge, and to complain of the apathy of the conservators in the matter.

COUNCILLOR HOWELL, of Hastings, has offered two acres and a half of freehold land on the Cornwallis estate as the site for a new hospital for Hastings and St. Leonards and the district.

M. BAKENOW, a physician, has been elected president of the Provincial Assembly of Eastern Roumelia. M. Bakenow has been a member of the Assembly since its foundation.

PRESTON INFIRMARY AND THE OPERATIVES.—The operatives of Preston employed in the factories and workshops in the town have during the past year contributed about £1250 towards the working of the Preston and North Lancashire Royal Infirmary. This amount has been made up by weekly contributions of one halfpenny.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—At the annual meeting of this Society, held recently, the following office-bearers were elected for the year:—President: Dr. Struthers. Secretary and Treasurer: Dr. Rodger. Librarian: Mr. William Fraser. Council: Drs. Beveridge, Jackson, Urquhart, Simpson, and M'Gregor.

THE HOWARD MEDAL.—At a meeting of the Statistical Society of London held on the 18th ult. the Howard medal and £20 were presented by the President, Sir Rawson Rawson, K.C.G.M., C.B., to Clement Dukes, M.D., B.S. Lond., Physician to Rugby School and Senior Physician to the Hospital of St. Cross, Rugby, for an essay on "The Preservation of Health as Influenced by Personal Habits, such as Cleanliness, Temperance, &c."

ROYAL ALBERT HOSPITAL.—The twenty-first annual meeting of the friends and subscribers of this institution was held at Devonport on the 17th ult. From the report it appears that the financial condition of the hospital is fairly satisfactory, the balance due to the treasurer, which at the commencement of the year was £280, being now only £29. The average number of patients daily under treatment has been 74·15, as compared with 74·68 in the previous year, and the average cost of maintenance has been £49 3*s.* per bed per annum.

DUBLIN HOSPITALS FETE.—The total receipts from the fête recently held were £491 12*s.* 4*d.*, and the sum available for distribution £410. On the principle laid down at the preliminary meeting of the committee—viz., that the twelve general hospitals should receive nine-tenths of the net proceeds, and that one-tenth be allocated among the five special hospitals—the amount received by each of the former was £39 17*s.* 10*d.*, and the latter £8 9*s.* 4*d.*

A MEDICAL SOCIETY FOR CARLISLE.—At a largely attended meeting of the medical men practising in Carlisle and its vicinity it was resolved that a Carlisle Medical Society should be instituted for the reading and discussion of medical papers and the exhibition of cases and specimens. On the motion of Dr. Campbell (Garlands), Mr. Page, the well-known northern surgeon, was appointed president for the first session. Afterwards Dr. Dowie was appointed secretary, rules were agreed to for the Society, and meetings were arranged to take place monthly from November to April inclusive.

LONDON HOSPITAL MEDICAL CLUB.—A very successful gathering of the London Hospital men took place recently at the Holborn Restaurant. Mr. Reeves was in the chair, and Dr. Langdon Down, Dr. Stephen Mackenzie, Dr. Charlewood Turner, Mr. Rivington, Mr. E. H. Fenwick, Dr. Bedford Fenwick, Mr. Ashley Barrett, and Dr. Milner Fothergill were among the company. The chairman, on giving the toast of the evening, "Success to the Club," said that he should be content if his chairmanship led to the members taking an active interest in the medico-political questions of the day—viz., first, the assertion of the rights of Members to a proportionate share in the government of the College; secondly, the formation of a good teaching university, which should also grant to London students the degree of M.D. or M.S. after a good average examination; and, thirdly, the question of a better representation of medical interests in Parliament. Some good speeches, music, &c., contributed towards a very pleasant evening.

LIVERPOOL MEDICAL INSTITUTION: GOOD *versus* WHITTLE AND OTHERS.—At a special general meeting of the Liverpool Medical Institution held on November 27th, (Dr. Gee, president, in the chair) it was unanimously resolved: "That the sympathy of their professional brethren is due to Drs. Whittle and Hutchinson in respect of the injury, anxiety, and loss sustained by them, owing to the trial of Good *versus* Whittle and others; and that by way of giving practical expression to this resolution a fund be opened towards reimbursing them the expenses which they have incurred in defending themselves." A fund committee was formed.

ROYAL MICROSCOPICAL SOCIETY.—At the last meeting of this Society, a new Lantern Microscope, the invention of Mr. Lewis Wright, worked out and manufactured by Messrs. Newton and Co., of Fleet-street, was exhibited by the oxyhydrogen light to an unusually large number of Fellows. The results obtained were, in the opinion of those present, greatly in advance of anything that has previously been obtained, far exceeding in definition the "Giant Electric Microscope" exhibited last year. This instrument was also exhibited at the recent meeting of the Quekett Microscopical Society, when the blowfly's tongue was shown from 6 ft. to 14 ft. in length, by the various powers, and the section of a dronefly's eye magnified 2500 diameters, or upwards of six million times.

HAMPSTEAD SMALL-POX HOSPITAL. — A largely attended meeting of the inhabitants of Hampstead, preceded by a torchlight demonstration, was held on the 3rd inst., to protest against the continued existence of the Small-pox Hospital which has been erected in the parish by the Metropolitan Asylums Board. A letter was read from the Hon. Sir John Day, Judge of the High Court of Justice, in which the writer stated that he fully sympathised with the objects of the meeting, and expressed his regret that his position as a judge precluded him from taking part in a public demonstration where litigation may be expected to follow. Resolutions favouring the immediate removal of the hospital, and approving a deputation to the President of the Local Government Board, were agreed to, and the meeting broke up with a vote of thanks to Viscount Enfield, who occupied the chair.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BROWN, JOHN, L.R.C.P.Lond. &c., has been reappointed Medical Officer of Health for the Bacup Urban Sanitary Authority, for the term of one year.

DUNN, THOMAS, M.B., has been appointed Assistant Medical Officer to Woodilee Asylum, Lenzie, vice William Gibb, M.B., resigned.

FRANCIS, LLOYD, B.A., M.B.Oxon., M.R.C.S., has been appointed Assistant Medical Officer to the St. Andrew's Hospital for Mental Diseases, Northampton.

HANDFIELD-JONES, M.B., M.R.C.P.Lond., has been appointed Assistant-Physician to the Chelsea Hospital for Women, vice London, resigned.

HARDIE, ROBERT, M.B., M.R.C.S., has been appointed Resident House-Surgeon to the Gateshead Dispensary, vice Robert Purdie, M.B., C.M., resigned.

HARPER, GERALD, M.D., has been appointed Additional Assistant-Physician to the Chelsea Hospital for Women.

JESSETT, F. BOWREMAN, F.R.C.S., has been appointed Surgeon to the Cancer Hospital, Brompton.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

Medicus.—The only public vaccinators in Scotland who are authorised to give certificates of proficiency in vaccination which are accepted in England and Wales as enabling the holder to become a public vaccinator are: Dr. William Husband, Royal Dispensary, Edinburgh Dr. James O. Affleck, New Town Dispensary, Edinburgh; Dr. Hugh Thomson, The Hall of the Faculty of Physicians and Surgeons, Glasgow; Dr. R. D. Tannahill, Royal Infirmary, Glasgow; and Dr. D. C. McVail, Western Infirmary, Glasgow. The Colleges of Surgeons and Physicians in London take no certificate except one given by the above, or by certified teachers of public vaccination in England.

Dr. J. H. Aveling.—Very soon.

"A NEW-BORN INFANT OF EXTRAORDINARY SIZE."

To the Editor of THE LANCET.

SIR,—In reply to the kind inquiries of Dr. Barnes respecting the above case, I have great pleasure in giving the following particulars:

The child was born alive, is still living, and is healthy. The mother had had two children previously, which were both of large size, but not weighed, and consequently their natal weight is unknown. The period of gestation was not thought to be protracted. The mother is a schoolmistress, aged thirty-three years, her diet consisting of very little flesh meat, and mostly of oatmeal porridge and milk. The delivery of the child was spontaneous, and without any laceration of the parts.

I shall be glad to answer any further inquiries respecting this case.

I am, Sir, yours faithfully,

Crewe, Dec. 2nd, 1884. GEORGE EDDOWES.

To the Editor of THE LANCET.

SIR,—While in Derbyshire I delivered a woman of male twins, the first weighing 17 lb. 8 oz. and the second 18 lb.; the placenta 4 lb., and an ordinary pailful of liquor amnii. Both were muscular, well-developed children. Before delivery, on placing the hand over the abdomen, the limbs of the children could be distinctly made out, and feeling as though there was but a sheet of brown paper between the hand and the children, giving the impression that it was a case of extra-uterine fœtation. The parents were of ordinary build, and about middle height. The mother had previously given birth to a boy of large size, but his weight was not taken; this boy was living at the time of the birth of the twins, and was a fine child. The mother progressed favourably, and at the end of a fortnight was up and as usual. The above was verified in the presence of another medical man.

I am, Sir, yours truly,

New Brompton, Kent, Dec. 1st, 1884. EDWIN C. WARREN.

To the Editor of THE LANCET.

SIR,—With reference to Mr. Eddowes' case, p. 941, and Dr. Barnes' observations, p. 985, may I be allowed to point out that several cases are noted in Section 1541 of the Medical Digest, where the weight at birth equalled or exceeded Dr. Eddowes' case.—Yours obediently,

Dec. 3rd, 1884. RICHARD NEALE, M.D.Lond.

"FOR CHARITY PATIENTS."

MESSRS. BURROUGHS, WELLCOME, AND CO. have communicated to us their willingness to allow each medical practitioner in the kingdom to prescribe at their cost to one charity patient enough of any of the various medicines prepared by them to last one month; or, if the prescriber prefers, they will supply two such patients for two weeks each. Should the patient be unable to pay carriage, Messrs. Burroughs, Wellcome, and Co. express their readiness to prepay delivery charges to the address either of the medical man or patient, as directed. A list of medicines from which selection may be made will be sent upon application to them.

St. David.—The secretary is Dr. Pocock, The Limes, St. Mark's-road, North Kensington.

"THE INCOME-TAX."

To the Editor of THE LANCET.

SIR,—I can quite sympathise with "In Morsu Diaboli," and have no doubt there are many other practitioners similarly circumstanced. The only escape in these cases lies in appeal, and that supported by clearly kept books, and a knowledge of what may and what may not be done in such cases. Having had bitter experience in the matter of appeal against income-tax assessments, I enclose for the assistance of your correspondent and others similarly troubled a copy of a form of account which I have used on three occasions, and with which I have been always successful. All the items of deduction were keenly criticised by the surveyor, but were all passed. Of course, in this copy the figures are imaginary, and are only intended as a guide. "In Morsu Diaboli" would be entitled to deduct cost of assistant, but would, I fancy, if his gross income is only £600, lay himself open to a charge of extravagant working in keeping an assistant, two horses, &c., in such a small, or at any rate unremunerative, practice. Another plain inference which he would have to be prepared to disprove would be the *bona fides* of the £600.

I am, Sir, yours truly,

Nov. 26th, 1884. TAXES.

INCOME-TAX RETURN FOR 1883–4.

Schedule D.—Appointments.

Medical Officer of Union	£65 0 0	
Public Vaccinator	57 10 0	
Medical Officer of Health	45 0 0	
		£167 10 0

Schedule E.—Profession of Surgeon, &c.

Gross income as per books	378 10 0	
		£546 0 0

Deductions.

Surgery Account:—		
Proportion of rent for consulting-room and surgery	£7 15 0	
Proportion of rates and taxes	1 5 0	
Drugs, bottles, and surgical appliances	70 0 0	
Horse and Stable Account:—		
Rent and taxes for stable and coachhouse	9 0 0	
Groom's wages	52 0 0	
Licence for carriage and groom	1 10 0	
Hay for two horses	27 10 0	
Corn, beans, bran, &c.	34 0 0	
Straw for bedding	4 10 0	
Shoeing and veterinary account	7 10 0	
Tolls	4 15 0	
Repairs to carriage	6 19 0	
Repairs to harness and saddlery	3 10 0	
		229 15 0
	£316 5 0	
Deduct £120, abatement allowed on incomes of under £400	120 0 0	
Income-tax payable on	£196 5 0	

The deductions (£229 15*s.*) and abatement (£120) together amount to £349 15*s.*, or nearly 65 per cent. of the total income.

The assessment under the different Schedules should be—

Schedule D.—On £167 10*s.* (less 65% = £107 10*s.*)	= £60 at 5*d.*	= £1	5 0
,, E.—On £378 10*s.* (less 65% = £241 10*s.*)	= £137 at 5*d.*	= 2	17 1
		£4	2 1

M.B.—The demand is an unreasonable one. The case is one for friendly settlement; but if that is impossible, payment of the full sum should be resisted. The nurse should show what she has lost or presumably lost, which, with a notice of six months, cannot be much.

VENTILATION OF SCHOOLS.

To the Editor of THE LANCET.

SIR,—The School Board here (of which I am a member) being about to erect new schools, I have been requested to advise as to the ventilation. Could you therefore advise me as to the best source of obtaining a pamphlet or book upon such matters?—I am, Sir, yours truly,

Paignton, South Devon, Nov. 30th, 1884. H. COLLINS, M.D.

*** The general principles to be held in view will be found in the articles on Warming and Ventilation in Wilson's Handbook of Hygiene (Churchill), and "Our Houses" (Cassell and Co.). Mr. Robson, formerly architect to the London School Board, has issued a work on School Construction. See also Mr. C. E. Paget's work on Healthy Schools, prepared for the International Health Exhibition (Clowes and Sons).—ED. L.

ARSENIC IN TEXTILE GOODS.

A TRIBUTE has lately been paid to the judgment of the medical profession in Sweden by the manufacturers of Chemnetz (Saxony), who petitioned the German Government to make representations to the Swedish officials regarding the inconvenience to business arising from the researches of their chemists as to the presence of minute quantities of arsenic in textile goods. It was suggested that in such cases the medical authorities should decide whether the proportion of arsenic was injurious to health, instead of the presence of that substance in minute quantity bringing the goods within the scope of recent Swedish legislation.

Dr. J. Ellis (Anaheim).—A subscription for the purpose mentioned has not been spoken of as yet.

Dr. Hosack Fraser is thanked for the intimation.

"SUPPOSED CANCER OF THE RECTUM IN A BOY AGED NINETEEN."

To the Editor of THE LANCET.

SIR,—I am much interested in Mr. D. M. Douglas's letter published in your last issue. He questions the diagnosis of cancer of the rectum on the ground that his patient was only nineteen years of age, and concludes his letter by stating, "I believe a case of cancer of the rectum in one so young is not on record."

In perusing the literature of rectal cancer Mr. Douglas must have overlooked cases, for several are recorded at an earlier age than that mentioned in his letter. Amongst others, I may refer him to two instances mentioned by Allingham ("Diseases of the Rectum," fourth edition), one in a boy of seventeen, and another in one aged thirteen. Godin (Mollière's "Traité des Maladies du Rectum et de l'Anus") observed a case in a patient of fifteen; while Quain (Pathological Society's Trans.) narrates a case occurring at sixteen years of age. I have myself recorded an instance in a boy of seventeen. In this case the patient was brought to me by Dr. Forbes of Rock Ferry. The symptoms had only lasted two months, and the boy was in fair general health. The course of the case was subsequently very rapid, the patient dying within twelve months of the first onset of the symptoms. Some weeks before death Mr. Reginald Harrison performed colotomy for complete obstruction. At the time of operation Mr. Harrison tells me that the pelvis was blocked up with a large mass of cancer, so that the diagnosis was verified beyond the possibility of doubt.

Rectal cancer is doubtless rare before the age of twenty, but I have seen many examples of it between that age and thirty. Mr. Douglas may be perfectly correct in concluding that the tumour which he describes is not malignant, but he does not tell us what he considers it to be. Should he remove the growth it would be interesting to hear from him what its nature proves to be.

I remain, Sir, yours truly,

Stratford-place, Nov. 28th, 1884. HARRISON CRIPPS.

To the Editor of THE LANCET.

SIR,—Mr. D. M. Douglas, in your issue of the 29th ult., says that he believes a case of cancer of the rectum in one so young (nineteen) is not on record. This is, however, not correct, for according to the Pathological Transactions, vol. i., p. 67, Mr. Busk exhibited a preparation at a meeting of the Society in 1846 taken from a boy sixteen years of age, who died of acute peritonitis. He had a tight stricture of the rectum three or four inches from the anus; it was accompanied by ulceration of the mucous membrane, and was produced by a large deposit of "medullary sarcoma" external to the muscular coat of the intestine.

May I suggest that the case recorded by Mr. Douglas may be one either of polypus or an erectile tumour, as the symptoms of polypus after attaining a certain development are dysenteric, and Dr. Tuckwell has recorded a case of erectile tumour of the rectum, in the *Medical Times and Gazette*, vol. ii., 1868, p. 195, which resembled chronic dysentery. Anyhow, from the symptoms recorded and the age of the patient "cancer" of the rectum is, in my opinion, negatived.

I am, Sir, yours truly,

Bicester, Nov. 30th, 1884. EDWARD COTTERELL.

J.—There is no English periodical. The American is *Journal of Cutaneous and Venereal Diseases* (New York; Wood and Co.), and the French, *Annales de Dermatologie et de Syphilographie* (Paris: G. Masson).

A CORRECTION.

To the Editor of THE LANCET.

SIR,—Kindly allow me to correct a misstatement of some remarks made by me in the course of the discussion upon Anæsthesia at the Medical Society of London on Monday, Nov. 24th, and which you reported in your issue of Nov. 29th.

Speaking of the so-called bichloride of methylene, I am reported to have said, "It was brought before the public under false colours." Now, Sir, my contention was that since this substance has been shown to be a mechanical mixture, and not a compound, it falls under false colours when represented to possess properties other than those inherent in dilute chloroform, or an exemption from the dangers which attend chloroform narcosis. I had no wish or reason to impute want of candour to those who have introduced, and who still advise, the use of bichloride of methylene.—I am, Sir, your obedient servant,

Gower-street, W.C., Nov. 29th, 1884. DUDLEY W. BUXTON, M.D.

Digitized by Google

MEDICAL CLUB TERMS.

Omega.—Concurrently with a less generous movement for extorting the greatest amount of work from medical men for the minimum amount of pay, there has been a creditable movement on the part of many of the older clubs to raise the remuneration of their medical officers from the old and quite inadequate figure of 2s. 6d. per member to from 4s. to 5s. We are sure that every member of a club would benefit by treating his medical attendant more liberally. When the family is included the terms should be less, but they should still be justly generous. Working people have no more valuable friend than their medical adviser, and they should give such terms as to keep good men.

Captain Tudor.—The line of treatment referred to has not been ignored by the profession. But no remedial measures are of equal efficacy in all cases and under all circumstances.

Mr. Lothbury should consult his solicitor. The question is a legal one.

VASELINE AS A SURGICAL DRESSING.

To the Editor of THE LANCET.

SIR,—I have seen, in your issue of Nov. 8th, under the above heading, an article by Mr. A. W. Mayo Robson of Leeds, and in your last issue his opinion confirmed by Dr. Herbert Stowers, London.

On looking over the cases enumerated by the former gentleman, I would beg to submit that it was probably not the use, but the abuse, of the vaseline which caused the irritation. In all these cases, with perhaps the exception of Case 2, I can quite understand the irritation being due to discharges pent up by the vaseline applied over the wounds. With regard to the second case, that of ophthalmia tarsi, I may state I have always taken the greatest care in using vaseline ointments in eye practice, owing to the frequency of its containing paraffin, and which I have myself seen frequently give rise to intense inflammation. It will therefore be seen that I submit that the dermatitis set up in the exceptional cases enumerated by Mr. Mayo Robson was probably due to the mechanical action of the vaseline, rather than to any chemical impurity, and that the same dermatitis might have been set up under the same circumstances by the application of lard, olive-oil, or tar, which might have no action beyond the confining of the discharge.

I am, Sir, yours truly,

Wigtown, N.B., Nov. 17th, 1884. WILLIAM J. PEDDIE.

To the Editor of THE LANCET.

SIR,—May I add a few words of further testimony to the irritating properties of vaseline? In different parts of the country—Yorkshire, Bucks, and Salop—I have met with several cases where its use as a dressing caused slight irritation of the skin. I have also found that some persons suffer from irritation and itching of the scalp if they use vaseline as a pomade. I have applied it myself on many occasions, and each time it caused a peculiar pricking itching, which lasted some hours. Vaseline is not so easily washed from the skin as are other greases and oils. Might it not, therefore, irritate by blocking the ends of the sweat or the sebaceous glands? Many of those employed in petroleum works are well known to suffer from irritation of the skin, and also from a form of epithelioma analogous to chimney-sweep's cancer. Has this fact any bearing on vaseline? I must add that I have used vaseline in hundreds of instances without any bad result. Indeed, mild stimulant properties may add to its value in certain cases.

I am, Sir, yours truly,

Leeds, Nov. 22nd, 1884. FRANCIS EDWARD CANE, L.R.C.P. & S.Ed.

To the Editor of THE LANCET.

SIR,—Will you allow me to support Mr. Mayo Robson's remarks upon this subject from an ophthalmic point of view.

I have noticed during the last year that acute irritation of the eye and eyelids has followed the use of vaseline as a base for the ointment known as "Pagenstecher's ointment" when applied to some cases of corneal ulcers. It is my practice to use this ointment in cases of corneal ulceration, and in rare instances I have noticed acute irritation follow its use, which was at once relieved by making up the ointment with lard instead of vaseline, each case being rapidly cured under this change. This accidental irritation seems to me to be so rare, and the great good in most cases to be obtained by compounding ointments in use for ophthalmic purposes with vaseline so undeniable, that I shall continue its use, expecting every now and then to have to change the base of an ointment from vaseline to lard.—Yours faithfully,

H. BENDELACK HEWETSON,
Honorary Ophthalmic and Aural Surgeon to the
Nov. 30th, 1884. General Infirmary at Leeds, &c.

A. W. will find what he requires, so far as the physiology of the subject is concerned, in the chapters on "Unconscious Muscular Movement" in Carpenter's work.

Dr. Eustace B. Thomson is referred to a letter in another column.

"M.B. PASS EXAMINATION, UNIVERSITY OF LONDON."

To the Editor of THE LANCET.

SIR,—A full account of the pathology, diagnosis, and treatment of Unilateral Hæmatokolpos will be found in *Fritsch's Diseases of Women*, an English translation of which can be had at Sampson Low's Library of Standard Authors.

I am, Sir, yours truly,

Newcastle Emlyn, Dec. 2nd, 1884. J. POWELL.

Mr. J. F. Allen (Pietermaritzburg).—The mixture is doubtless inexpedient, and may be productive of harm to tender stomachs; but we do not remember any reported cases of injury having resulted from the ingestion of the agents in small quantities.

AN APPEAL.

To the Editor of THE LANCET.

SIR,—The following is a copy of a letter I have sent to the Royal Medical Benevolent Society in the hope of obtaining for Mrs. Fenton of Whitgift the annuity of twenty guineas allowed to the widows of medical men in poor circumstances; and I am further desirous of supplementing this small allowance by getting up a subscription which would enable me to pay her a further sum of eight or ten shillings weekly for her few remaining years.

"The late Wm. Fenton practised in Bayswater for some ten years, and then removed to Whitgift, Yorkshire, where he was in practice for about fifteen or twenty years, and up to the period of his death, which occurred at the commencement of this year under the following painful circumstances. Whilst examining a broken portion of the brass harness fittings of his trap, before starting on his usual rounds, he very slightly scratched one of his fingers, but thought nothing of it. Shortly after he had to perform a minor operation upon a club patient suffering from malignant disease. This occurred on the Thursday; on the Friday and Saturday he was feverish and ill, with swollen arm, &c. Dr. Blair of Goole was sent for on the Sunday, and on Monday the poor fellow died from blood-poisoning, and I believe his club patient died about the same time. The practice was a small country one, and, sad to say, no provision had been made for the widow, who is left entirely destitute, and, had it not been for the kindness of one or two personal friends, might now have been in her grave or the workhouse. Mr. Fenton's estate became insolvent, and no purchaser has been found for the death vacancy, although advertised for sale and offered for £100. Mr. Williams, the vicar, and Mr. Blair of Goole will fully endorse all I have here stated."

I propose drawing up a concise statement of the case, and having 1000 copies printed and forwarded to those wealthy members of the profession who would be likely to sympathise with so distressing a case. I ought further to add that Mrs. Fenton is old, and has outlived every member of her family save one.—I am, Sir, yours faithfully,

JOHN BAKER, M.R.C.S.
Heidelberg House, West Brighton, and Abingdon Villas,
Kensington, Nov. 21st, 1884.

ANOTHER APPEAL.

To the Editor of THE LANCET.

SIR,—Three years ago a young surgeon practising in New Zealand died, nine months having elapsed since the death of his wife. Two little orphan boys, aged three and four years respectively, were at once sent home to England to their grandmother, the widow of a clergyman, herself in delicate health, with scanty means of support. With praiseworthy energy, this good old lady at once set about a vigorous canvass to get one of the lads into the Wanstead Orphan Asylum, and was, happily, successful. She is now most desirous, ere she dies, that the other little fellow may find a home in the same institution as his brother, so that the fatherless and motherless boys may at least know and see something of each other during their childhood. A sum of £180 will secure the fulfilment of this very natural wish, if raised before March next. The British Medical Benevolent Fund, which has already on two previous occasions given assistance, has to-day promised £20 if the remainder of the sum required is forthcoming, and I venture through your columns to invite others to take part in this good work. I shall be most happy to give fuller information to anyone desiring it, and to take charge of contributions which may be sent to me for the purpose I have named. I am, Sir, your obedient servant,

STAMFORD FELCE.
Kenmure Lodge, Elgin-road, St. Peter's-park, W., Nov. 25th, 1884.

CASSAN *v.* FYFE.

To the Editor of THE LANCET.

SIR,—The case of "Cassan *v.* Fyfe," to which you refer in your issue of Nov. 22nd, is one of those unfortunate and unpleasant affairs that ought never to occur. Mr. Cassan has been at considerable loss in his efforts to clear himself from imputation cast upon him; and I am making this appeal through you to the profession thinking that it would be desirable to assist our professional brother in the expenses to which he has been necessarily subjected. I know there are those who will gladly respond; and I shall be most happy to receive for him any such expression of sympathy, which will be duly acknowledged, as well as in your pages, if you will permit.—I am, Sir, yours faithfully,

H. F. LANCASTER, M.D.
Neston Lodge, 275, Lewisham High-road, S.E., Nov. 25th, 1884.

To the Editor of THE LANCET.

SIR,—Who will be the rescuer? Our profession has well earned the title "noble." How more nobly can it vindicate its claim to that proud distinction than by upholding the reputation of an injured son? Who will help Cassan? Given the opportunity, there are, I feel certain, many who from their abundance will spare a trifle for this cause. You have already won a heap of thanks by your congratulations and your assurances that the sympathy of the profession will be given so generously to him. With many thanks for what you have already done in this case, and for your readiness at all times to maintain the dignity of our calling, I am, Sir, yours faithfully,

Nov. 24th, 1884. DUM VIVO VIVAT.

OVERCROWDING IN NEW YORK.

FROM a report which has recently been presented to the Tenement House Commission of New York City, it appears that 562 tenement houses visited by the inspector contained 5050 families and 20,117 persons—an average of nine families and over thirty-five persons to each house. In many of the houses the occupants reached four times this number. In 90 per cent. of them the closets were in foul condition, 10 per cent. being most dangerous to the health of the inmates.

Filter is referred to the report on the subject in THE LANCET of 1867—Jan. 12th, March 23rd, and July 6th.

"MEDICAL EDUCATION IN AMERICA."

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 18th mention is made, in one of your annotations on the articles written for *Le Progrès Médical* by M. L. Thaon, of the state of medical education in America. You were rather misled by the papers in question when you state that medical education receives no support from the Government here. Some years ago the National Government set apart a large amount of land, the income of which goes to endow one university in each State, the university to consist of five departments—viz., a college of literature and the sciences, a college of the fine arts, a college of agriculture, a college of law, and a college of medicine. The result of this is that many States have medical colleges supported by the Government; for although the income from these lands is considerable, it is not sufficient, and the State Governments appropriate more or less every year to support the different departments of the university. These medical schools are all practically free. Among them I might mention one at Boulder, Colorado, a town of about 6000 people; Iowa City, Iowa, a town of 10,000; Lincoln, Nebraska, a town of 18,000; Ann Arbor, Michigan, a town of 15,000. There are two or three others supported by the Government—that is, by the State. With one exception, the ones mentioned above are absolutely without any hospital advantages. The time demanded generally is three years, although some of these State supported schools, like many others, grant the M.D. degree after attendance on two courses of lectures. I need not say that there is more theory than practice taught in these schools—I am, Sir, yours truly,

GEO. H. SIMMONS, M.D., L.M.Dub.

Lincoln, Nebraska, U.S., Nov. 6th, 1884.

Dr. Angus Macdonald.—No doubt we shall be able to comply with the request of our correspondent.

"NOTE ON TRACHEOTOMY."

To the Editor of THE LANCET.

SIR,—On reading my Note on Tracheotomy, which you were good enough to insert in your last issue (page 951), I see that, when alluding to Dr. Ewart's suggestion, I omitted to say that he recommended the mouth to be rinsed out "with oil." Will you kindly allow this my correction to appear in your next number, and oblige yours truly,

Cavendish-square, W., Dec. 1st, 1884. JOHN W. OGLE, M.D.

Mr. F. P. Atkinson.—The drug has, we believe, been already employed for the purpose suggested.

Dr. C. C. Tite (Nashville) will find the notice on page 855 of THE LANCET for Nov. 8th.

A QUERY.

To the Editor of THE LANCET.

SIR,—Can you or any of your readers inform me where I shall find a record of Dr. Freud's experience of the uses of cocaine in dipsomania, &c.?

I am, Sir, your obedient servant,

Nov. 30th, 1884. T. G. T.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Durham, London; Messrs. Steel and Jones, London; Dr. J. "Bradshawe" Lecture

ON THE

PATHOLOGY OF CANCER.

DELIVERED AT THE

ROYAL COLLEGE OF SURGEONS,

On Thursday, Dec. 4th, 1884,

BY WILLIAM S. SAVORY, F.R.S.,

SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

"WHAT'S in a name?" Not very much, perhaps, in the sense in which Shakespeare puts the question into the mouth of Juliet. No great danger, probably, or source of error, when the matter under consideration is as simple and clear as the odour of a rose; but it is surely otherwise when ideas involving far larger and more complex issues come to be expressed by a single term. It is often said, and indeed with truth, that for one's self it is no matter what you call a thing so long as you understand the subject or nature of it; but this always signifies very much to others who may not so clearly comprehend it. It would be easy enough to illustrate the tyranny of phrases in the study of pathology and in the practice of surgery; for here the power of words for mischief is sometimes seen in a twofold aspect. Not only in the perpetuation of error, but in the maintenance of confusion too. Certain terms and titles have not only given the stamp of currency to false doctrines, but by the changes they are prone to undergo, and have undergone in their meaning, they signify different things at different times, and at the same time different things to different persons. I say it would not be very difficult to find abundant illustrations of these remarks, but I will take now only the one that is to be found in the terms "local" and "constitutional." In a general sense, perhaps, these are sufficiently intelligible, as when we speak of constitutional disturbance from local disease. When neither the patient nor the surgeon can detect any evidence of mischief, except in a limited portion of the body, such affection may very well be termed local. When the patient is conscious, or the surgeon can discover, that the functions in general are disturbed, the condition is very fairly expressed by the term constitutional. But when these same terms, local and constitutional, are employed more definitely, and in relation not to phenomena merely, but to the nature and origin of disease, difficulties soon appear which lead to error and confusion. The oldest, the largest, the plainest, and most popular division of tumours is into innocent and malignant growths; and, although it has always been easy to show that these two great classes often approach very closely, and even pass into each other, still, in the main, the several broad and well-defined lines of demarcation have been sufficiently obvious. Not only surgeons, but the public, have come to understand the great point of distinction. The crucial question is continually asked, if the tumour is removed, Will it come again? But then, of course, to those who think on these things, the further question inevitably rises, Why are tumours in their nature and history thus different? Whence the cause of such a contrast? What does it mean? And these deeper questions have been replied to, over and over again, by the phrases local and constitutional. The innocent tumour is a purely local one. There is no extension, save by the growth of the sensible mass. Its substance and whole influence lie within a small space of the body, which can be clearly defined. To this place it is strictly limited, and if it be removed from this, it is gone for ever; but of the malignant tumours none of these conditions can be affirmed. Whatever may be true, at any given time, of the sensible mass, the existence of the disease is not so limited; and thus, in contrast to innocent ones, malignant tumours have been called constitutional. But then, when the inquiry is carried further, and some explanation of constitutional, in this sense, is demanded, when it is asked in what way the word constitutional advances our knowledge beyond the term malignant, it must be confessed that the answer is not altogether a satisfactory one.

Many of us can remember the celebrated discussion on cancer at the Pathological Society, and the fact that seems to stand out in it most clearly is, that then, as usual, the term constitutional was employed by different speakers in widely different senses. And, moreover, I think it might be shown that the different ideas which different speakers associated with the term constitutional were mainly due to the relative importance which each speaker respectively attached to certain features of malignant tumours. Of cancer, it was at the outset affirmed that the all but certainty of its recurrence, remove it as we will, its hereditability, its frequent association with other forms of irregular growth, its often rapid diffusion, its power of infecting the system—all, in fact, that we see in the life of cancer—naturally lead to a belief that the disease must, from the first, be more than a mere local tissue change. But then, again, in view of the hereditariness of cancer, of the constancy and of the method of its recurrence, and of the insusceptibility of bodies generally to the inoculation of cancer, the word constitutional was held to be equivalent to the total constitution of the body, that the constitution is, in short, the man; all that gives to him his individuality. But, again, the assumed facts that in cancer there is no distinct or specific anatomical or structural element, that neither plurality of tumours nor the property of recurrence *per se* is destructive, that cancer is all-pervading and appears as a disease, the one essential character of which is dynamical, such facts suggest strongly to some that cancer is a disease of the blood, or even that hereafter it may be found to be in close alliance with the so-called zymotic affections. In favour of this view has been added the observation of the mode in which secondary cancerous tumours grow; not as mere grafts undergoing increase, but as a definite sphere of the secondarily affected organ undergoing changes in its own elements, and growing, by way of such elementary changes, into the likeness of the primary tumour. Furthermore, this view appears to be strengthened by a comparison of cancer with syphilis. Taking, on the other hand, a chancre inoculation, say of the lip, with affection of the lymph glands, followed after a certain number of years by gummata throughout the body, and taking, on the other hand, an epithelial cancer of the lip with its secondary affection of lymph glands, and subsequent identical affection of, say, the lung or liver, it is asked, Can we affirm that these two cases differ more than we might reasonably expect two species of morbid poison to differ? This is even suggestive of a contagium from without. And yet further, in the manner in which it is inherited, a resemblance has been found to syphilis, gout, and tubercle. Once more. In face of the fact that the hereditary transmission of cancer must mean that it is conveyed from parent to offspring, through the ovum or spermatic fluid, it must exist in the individual before the formation of the blood. And it has been maintained that the term constitutional, or all-pervading, may be true enough in regard to the ovum, but that it ceases to be true of the adult, because then we can realise the "condition of localisation" in the various tissues of the body.

Thus, with such different interpretations from such high authorities of the term constitutional, it cannot be allowed that it has any precise or definite signification for us, and furthermore, I fear it must be admitted that when the several grounds on which these various forms of belief are based, are critically examined—as, indeed, some of them were in the discussion alluded to—they will hardly be found adequate to the purpose in view. For example, that a disease is hereditary is no proof that it is constitutional in any of the senses in which the term has been employed. Otherwise the term constitutional must be given to every form of tumour which has been shown to be occasionally hereditary; and thus the significance of the expression, at least in its relation to cancer, would be lost. Neither does it appear to me that the view is supported by the manner in which cancer often proves to be hereditary. Although the fact of the occasional hereditary transmission of tumours is common to all of them, it has been pointed out that there is a difference in the manner of transmission of tumours which are called local and of cancers; that when a local or innocent tumour is transmitted it reappears in the same tissue, if not in the same place, in the offspring; whereas no such limitation is observed in cancer. But the difference in this respect seems to me to be more apparent than real, and, such as it is, I think may be

Digitized by Google

explained by the nature of the cancer substance, of which I shall speak presently. When innocent tumours are transmitted, they often appear in the offspring in widely different parts, although, for obvious reasons, somewhere in the same tissue; and cancers, when transmitted, have a strong tendency to reappear in the same part; perhaps in half the instances in the breast. The difference, after all, appears to be one only of degree, and if the current view of the relation of cancer to epithelium, and of sarcoma to connective tissue, be correct, of a degree perhaps not very significant. For it may be said that no kind of tumour which is hereditary is limited to a particular place, and every kind of tumour which is hereditary is limited to a particular tissue. Then its recurrence after removal and its dissemination—the features which place it in such striking contrast to the tumours called innocent—in a word, the signs that are generally held to indicate an affection of the system—cannot be shown, I think, to be the usual attribute of cancer in the earlier stages of its history. If, in its course, cancer becomes thus all-pervading, this does not involve the admission that it was constitutional at the outset; for a disease may be local at one time and constitutional at another; and this is a point which, I venture to think, requires to be carefully distinguished. The characters which a disease presents at an advanced stage of its progress is one thing; its mode of origin is quite another; and, in the case of cancer, I shall try to show that this distinction is a necessary one, and of fundamental importance. Nay, even in a disease which in an early period of its history is emphatically recognised as constitutional may, I suppose, in the earliest stage of all be considered local. For in whatever relation the induration of a chancre may stand to the infection of the system in syphilis, it will, I take it, be generally allowed that after inoculation and certain local changes consequent thereon a sensible period, though it may be a very short one, elapses before the poison becomes all-pervading. If the arguments in favour of the view that cancer is a constitutional disease be examined, it will appear, I think, that many of them are valid only in regard to the more advanced stages of cancer. The evidence in favour of the view that when cancer first appears in a body it is as a constitutional disease seems to me far less clear and cogent.

Now, let us discard for a moment these terms local and constitutional, and let us approach the study of cancer from another point of view. Amongst the many attempts at an adequate classification of tumours there is one which is founded on their structure, on the character of the elements of which they are built up. The fact is sufficiently clear that various tumours are composed of structures or tissues, which, in sensible characters, are completely identical with some one or other of the normal tissues or structures of the body. Fatty and fibrous tumours are familiar examples of these. I suppose portions of fatty or fibrous tumours may be placed under the microscope side by side with portions of natural adipose or fibrous tissue, and no histologist, who understood his work, would venture to say that he could distinguish between them. But, again, it is clear that certain tumours present structures which are not identical with any of the adult structures of the body, but which may be distinguished from any of these by competent observation. Hence the famous classification of tumours into homologous and heterologous growths. But further explanation is necessary here. In this view the term heterologous has been commonly employed in its full meaning; to signify that tumours so-called do not in their structure resemble any of the natural tissues of the body; it should, I think, be as I have already said—any of the adult or fully formed tissues of the body; for in truth, and this is of the first importance, these heterologous tumours, in their sensible structures, do resemble some natural tissues when in an embryonic or immature state. Just as portions of homologous tumours may be mounted side by side with portions of certain adult tissues, and no distinction between them can be discovered, so portions of heterologous tumours may be mounted side by side with portions of certain embryonic tissues, or tissues in course of development, and no distinction can be drawn between them. Let me be understood in this. I am not referring to the arrangement of the elements in a tumour, but to the sensible characters alone of the ultimate elements. A carefully prepared section of cancer or sarcoma in a typical state has characters, of course, by which it may be distinctly recognised. These characters of arrangement have been described over and over again, and are now familiar to all. But to these I do not now refer. My remarks here are confined to the primary forms themselves; to the physical characters of the ultimate elements of structure, not to the mode in which they are arranged; in short, to the so-called cells, either in their typical form or in some of the earlier changes they undergo. So, then, of cancer and its allies, of the various forms of sarcoma, it may be affirmed that they consist of structural elements which in their sensible characters correspond to certain natural structural elements in a rudimentary state.

Now, if we pass, for an instant, from the study of tumours to a comparative view of the phenomena of life, either in the vegetable or animal world, we must remark in various individuals of either kingdom a wide diversity of structure; not only a wide diversity in separation of organs, or in complexity of combination, but a diversity yet wider, even more general, in truth universal, in the ultimate anatomical elements of which they are constructed. From a simple cell, or cluster of cells, we pass through various tissues which have been reached by further stages of development, until we arrive at the most elaborate, or highly specialised structures; for instance, at the spiral vessels of plants and at striated muscle of animals. Again, by such a survey, the fact is revealed that there is the widest difference in the power of multiplication, or propagation, among the various forms of animal and vegetable life; and, furthermore, that a relation may be observed between the simplicity of original structure or degree of development and this power of reproduction; that the creatures whose structures and mode of formation are simplest, which are most akin to the primary elemental form, can increase and multiply with most rapidity and ease. On the contrary, in those creatures called highest, which consist of structures and organs most elaborately formed and highly specialised, the power of growth and reproduction is most limited. And yet, further. In such a study a deep difference is observed in the relation which such different creatures hold to the conditions under which they live. There is, of course, a constant action and reaction between them, and what are called the external agents of vital action, both material and dynamical. All are dependent on, and influenced by, food, air, and the operation of the physical forces; but this in widely varying degrees. While the higher or more complex creatures are less influenced in their character by these than are the lower or simpler, the lower or simpler are less dependent on these than are the higher or more complex. The simpler forms can exist, can maintain life, under far more variable conditions than the more elaborate ones. Their power of endurance is manifestly far greater. Who needs to be reminded of illustrations of this in either the vegetable or animal kingdom? Compare the power of endurance of exposure, deprivation, and extreme change of the simplest plants, with the tenderness and susceptibity of the more elaborately developed ones. In the animal kingdom, even among invertebrata, compare the simpler with the more elaborate forms of life, in their power of sustaining deprivation of food, and air, and heat; and, above all, witness the striking contrast in this respect between fishes and reptiles on the one hand, and birds and mammalia on the other.

Now, this great law of nature, for such it seems to be, governs not only the various individuals of the living kingdom, but it is in force also in the several tissues and structures of the same individual. Note now how widely they vary, not only in design and pattern, but in their degree of elaboration or complexity. Compare, for a single instance, fibrous tissue and striated muscle; and now note, too, the wide difference between these various tissues in their power of reproduction. The simplest of them may be said to be capable of perfect reproduction. Witness, on this side, the result of the division of a tendon; witness, on the other, the result of the division of muscle. It is doubtful perhaps whether, in such circumstances, muscle can ever be perfectly restored. It is certain that, as a rule, it is not; but that, in repair, its place is supplied—and observe the significance of this fact—by the lower or simpler form of tissue, the fibrous. Then, further, observe the relation in which this power of repair or restoration stands to the mode of original development, whether in the creature as a whole, or in the several tissues of which it may be composed. There is surely a relation, but an inverse one, between the extent of change through which any individual or structure passes in the course of its development and, when fully formed, in its power of reproduction after mutilation. In the vegetable kingdom compare, in their power of recovery after mutilation, the simpler cellular

Digitized by Google

plants with the higher exogens and endogens, and in the animal kingdom the like power in polyps, worms, and amphibia with that of birds and mammalia. And let me remind you here of the significant fact that this power varies, not with type of organisation, but with grade of development; not with the relation to each other of parts and organs, but with the nature and extent of change through which the several creatures in the course of their development pass. And what is true of creatures as a whole is also true of the several tissues of which they are constructed. Compare the power of recovery of the cellular tissue and woody fibre of plants, or of the fibrous tissue or even nerve and muscle of animals with their mode of development. It would seem indeed that in proportion to the amount of force engaged in original formation, so is the power of subsequent repetition reduced; or otherwise, that there is an inverse proportion between the power of attaining a high grade of development and the power of reproduction. So that while on the one hand, from a knowledge of the mode of development, one might foretell the capacity for repair after mutilation of an individual or tissue; on the other, from a study of the capacity of repair, whether in the individual or tissue, one might be able to judge of the degree of change through which it passed in the course of its original development. And it may be affirmed of individuals and their tissues that the lower the grade of development the greater is the power, not only of reproduction, but of endurance of life; that in proportion to the extent of change which any individual or tissue passes through in the course of its development, so not only is its subsequent power of reproduction limited, but so also is its maintenance of life dependent on the special conditions under which it exists.

Now of tumours, it may be remarked in the first place that, various as they are in structure, they almost invariably consist of one or more of the simpler tissues—of tissues of comparatively simple structure, and whose mode of formation does not involve any very elaborate series of changes. Among the tumours called homologous, or those which consist of adult or fully formed tissue, fibrous tissue in its various forms and adipose tissue are very common; muscular tissue very rare. When muscular fibre appears in the substance of a tumour the plain, or unstriped, or simpler form of fibre is far more common than the more elaborately developed striated fibre, and perhaps in most of the instances when either of them is found their presence is due rather to the inclusion of normal tissue in the tumour during its growth than to an independent formation or distinct outgrowth of muscle. Again, in glandular tumours, which are by no means uncommon, it is the acinous portion of the gland, that which in original development is first of all formed, which is chiefly represented in the substance of these tumours; ducts which are more complex are not very often completely produced. Still the tissues which compose these innocent tumours, comparatively simple as they are, nevertheless are wont to obtain their mature or adult condition; so that although, being of a comparatively low grade of development, they are readily produced, and can therefore grow almost without limit, yet withal, being fully specialised structures, their life more immediately depends on certain external conditions. But the structure of cancer and its allies is characterised by the presence of the lowest and simplest of living forms. The so-called cancer cells, the structural elements of cancer, are the very type of the rudimentary or embryonic form of tissue; and beyond this early stage the typical cancer cell seems never to pass. Both in positive and negative characters it corresponds to the simple animal or vegetable cell. In its indifferent endowments, in the total absence of any special function, in its tenacity of life and endurance of change of external circumstances, it very closely resembles it. If one were asked to enumerate the characteristic properties of the lowest and simplest forms of life, of the cell, I think reference would be made to rapidity of growth, to power of reproduction, to wide extension and dissemination. And do not these characters form the prominent features of cancer in its worst or most malignant form? The absence of any attempt at what is termed differentiation or specialisation is in accordance with its surpassing power of multiplication and tenacity of life; and, as we pass from cancer through the more malignant to the less malignant forms of sarcoma, we find a departure from the typical form of cell to be associated with more limited power of mischief. As the elements of a tumour become fusiform or spindle-shaped, as the first steps in development towards the formation of some special kind of tissue are taken, so is the property of dissemination, or the power of living under various conditions, restricted, until, as we pass further on to the production of distinct fibres, as the power of individual development advances, the attribute of indifference to surrounding conditions, or to its environments, disappears, and the elements of the tumour become limited to a particular place. It is from first to last local, or what we call innocent.

But one word further on the so-called cell of cancer. The history of this word cell, in its relation to physiology and pathology, is not without interest and importance. When the famous cell theory was first set forth, a cell was very clearly and accurately described. Schwann, and many of his successors, in their definition of a cell, took care to leave no doubt on what they regarded as its essential structure. At length, however, certain facts were established which were fatal to the cell theory as it was then understood and accepted by all. It was shown, for instance, that in the development of muscular fibre cells had no share, and it then appeared how deeply rooted in the minds of physiologists this great doctrine had become. To me, at least, it seems that mischief has arisen from the proceeding by which an attempt has been made to evade the fatal objection opposed to it by facts. The scarcely ingenious scheme has been devised of modifying or enlarging the definition of a cell so as to make it include structures which really can have no claim whatever to the title of cell in any fair signification of the word. Cells have more recently been described as mere masses of protoplasm, each around a nucleus, and the existence of a wall or limitary membrane as an integral part of a cell has been quietly ignored. To me it seems, in all candour, that no better reasons for applying to such a structure as this the term of cell can be given than that such compromise is essential to the maintenance, in some shape or other, of a so-called cell theory. It is affirmed indeed that "the existence of animal cells destitute of envelope, although more insisted on of late years, has been all along recognised in the study of cell development, and was expressly pointed out by Schwann himself." But although it is true that Schwann admits, in more than one place, that the presence of a cell membrane cannot always be demonstrated—as, for instance, in the following passage: "Many cells, however, do not exhibit any appearance of the formation of a cell membrane, but they seem to be solid, and all that can be remarked is that the external portion of the layer is somewhat more compact"—yet, I think, a candid study of what he has written will show that he never contemplated, by his theory, the inclusion of such facts in development as appear to be now established. If it were true, as Schwann and his more immediate successors believed, "that there is one universal principle of development for the elementary parts of organisms, however different, and that this principle is the formation of cells," then it would be all very well to admit the occasional existence of such structures imperfectly formed without doing much violence to the doctrine. But it is altogether different when, in the development of certain most important tissues, no cell in any form appears, to persist in applying the term to simple fragments of protoplasm, a term which has been long and properly associated with a definite and different structure. It may be suggested that the alternative of throwing over an exploded doctrine is preferable to the confusion which must inevitably result from such vague and inaccurate employment of words. Surely the cell theory, as it has been long understood by all, is no longer tenable. Why attempt to avert its fate by what cannot be characterised otherwise than as a perversion of language?

And this question of the constitution of these so-called cells points to the further fact which I believe to be at the root of the erroneous view of their nature: the changes in aspect and character which living substances undergo at death. The conclusion has, for the most part, been too hastily and unconditionally accepted that the characters presented by tissues after death, and even after treatment by powerful reagents, are those that naturally belong to them during life. The structural changes which ensue on the cessation of life have, indeed, been long recognised in certain nerve fibres, but hardly, I think, anywhere else; yet I believe it to be, in some degree, common to all tissues. There can be no doubt, I think, of the fact of great change in striated muscular fibre; and some years ago I tried to show that the nucleus of the red blood cell in those vertebrata in which it is supposed to be constant has no existence during life and health. And I believe that the same fact is true of many forms of the

Digitized by Google

nucleated cell; of the cancer cell, for instance, here. During life these are but fragments of simple protoplasm, the substance of which, uniform during health and vigour, separates at death into cell wall, nucleus and contents, after the manner of the coagulation of the blood and the rigor mortis of muscle. Now, I say, this seems to apply with especial force to the pathology of cancer. Its elements are, in truth, not differentiated even into complete cells. When fresh and unaltered there is no distinction of cell wall and cell contents. In the living particle I doubt whether there is even the distinction of a nucleus. In short, they are, I believe, but separate fragments of protoplasm equal to, but not higher in rank than, the amœba or white blood cell or the utricle of the plant. I say this view especially concerns us in its relation to the pathology of cancer. Cancer, strictly so named, we have been taught is the outcome of the epithelial tissues. Now, fully formed or mature epithelium is undoubtedly composed of cells, of individual structures showing distinctly enough cell wall and nucleus. And yet even here development into a complete cell is through the shortest and simplest changes. Then see how even this contrasts with the so-called cell of cancer, for these fragments of cancer protoplasm are but the embryonic or rudimentary form of a cell of epithelium. Their power of individual development does not reach even to this level. Judge, then, what their power of endurance and of multiplication must be. Then, again, this concerns the relation which the cancer cells bears to some cells of natural structures. If the cancer cell were really a complete and fully formed cell in the proper acceptation of the term, it might be argued that in this view it should have no further power of malignancy than, say, a fat cell. But herein consists the difference. A fat cell, although a comparatively simple structure, is yet one thoroughly specialised. It is no longer indifferent substance, but its life is devoted to a particular function. It is fully formed, adult, mature. So, again, with the cells of secreting glands. They probably are not, and, I think, for the same reason, so far removed from cancer cells as are fat cells. But still, gland cells are not in a state of indifference. They are so far specialised that they have a definite function, and clearly the whole purpose of their life is devoted to its fulfilment. I will only add, as reference to this matter, that I believe the same view may be carried into the structure of sarcoma. The characters which the elements present after death, still more after the action of various reagents, are not those which belong to them during life. The so-called fusiform and spindle-cells are, again, but separate fragments of protoplasm, altering their shape in the first step towards the production of some definite tissue.

Seeing that no satisfactory explanation of the clinical facts of cancer can be given by way of the constitution or blood or germ, some have sought to find it in the mobility and dispersion of the cells. To account for the infection of neighbouring and distant parts, and ultimately the contamination of the system, attention has been called to the fact that the cells are dispersed around a cancer tumour, and that the direction and rapidity of dispersion will vary according to the density of the tissues, and the abundance of connective tissue spaces, or of lymphatic or vascular networks in which it lies. We have been reminded that cancer is, for the most part, a structure infiltrating itself amongst the tissues in which it grows, not surrounded by a capsule or limitary membrane of any sort, as are so many non-infecting tumours. Once set free, it has been argued, the cells may travel either along the lymphatics to the glands, or through the surrounding tissues in the direction of the least resistance; or they may pass through the bloodvessels into the general current of the circulation. At times, too, they may pass through cavities by gravitation. No doubt such physical conditions as those alluded to may have some influence on the rate and direction of the distribution of cancer, but all of them together will surely not suffice to explain the clinical facts. A comparison of the dissemination of cancer with the wandering of white blood cells, which, indeed, has been brought forward to support the view, seems to me, when considered, to destroy it. The white cells wander freely, but they do not form new and distinct growths composed of masses of white blood cells over the body; but they soon change, are either developed into some form of existing tissue, or otherwise disappear. It is, on the contrary, in the very nature of the cancer cell not to advance in development, but to multiply. Moreover, it has been pointed out that there are cancers and sarcomas which multiply themselves in distant and dissimilar parts, whose physical condition looks as unfit for travelling as any that could be named. It is quite true that, in the typical forms of cancer proper, the cells themselves are free and mobile in the spaces within which they are enclosed. But when we study malignant tumours as a class, and compare them with innocent ones, it cannot, I think, be affirmed that there is anything like a constant relation between the rate and extent of their distribution and the mobility of their cells. Again, the attempt has been made, by Cohnheim, for example, to explain malignancy by assuming that the physiological resistances to invasion are somehow diminished. He argues that germs of cancer implanted into fresh tissue are sure to perish when the changes which go on in the tissue are normal. Their development implies that the tissue changes in which they live and grow have ceased to be normal. But there is no evidence of this in relation to tumours, and even, if established, it would not afford any adequate explanation of the malignancy of cancer. Why should it not apply to other tumours which are innocent? It does not touch the question of distinction between these and cancer.

The phenomena of cancer, then, the facts of its clinical history cannot be adequately explained by any reference to the constitution in any of the senses in which the phrase constitutional has been employed. The arguments in favour of this view in any form fail from want of precision. In the sense that an original flaw or defect exists in the vital endowments of a part it may be admitted to be true; but in this sense innocent tumours must be admitted to be constitutional, and so must every individual feature be which is hereditarily transmitted. Neither can the clinical facts of cancer be explained by regarding it as an affection of the blood. Inasmuch as this view has some advantage over the other in precision, so it fails more conspicuously to cover all the phenomena of the disease. Nor can the malignancy of cancer be explained by the mere mobility of its elements, for ceaseless change and constant transmission is the law of life everywhere. All fluids, all solids, the loosest and the firmest textures, are in continual motion. Look where we will we know full well that the appearance of stability and endurance is illusory. Vital action is inevitably associated with molecular movement. Freely, then, to cancer we may grant great mobility of its elements; but to explain its clinical facts we require much more. And I, at least, believe that what is wanting here is to be found in the nature and vital attributes of its so-called cells, or of the formless plasm out of which they come. For this matter, or these fragments, possess an ability of living after the fashion of the lowest and simplest forms of life. When we call these structures embryonic, it must never be forgotten or overlooked that this term has reference only to their position in the scale of life, to their grade of development. They resemble, indeed, during the whole period of their individual existence embryonic substance in the simplicity of their physical characters. But they differ in the widest possible way from embryonic structures in their vital attributes and life history: in the almost, if not quite, complete absence of change of structure or of endowment; and it is in this contrast that their power of evil becomes manifest. The great feature of embryonic tissues is in the advance from a simpler to a more complex state; to the formation of a higher structure, with more exalted or, at least, with more special functions. In short, their great vital endowment is the power of development. But the protoplasm and fragments of cancer are just what they are, because they have none others. They cannot "rise to higher things," and, according to a law of nature, they obstinately retain life and, in unbroken force, the power of propagation. Their power of growth is inversely to their power of development, and growth here is but synonymous with multiplication; for, as in the lowest and simplest forms of animal life, in structures composed of simple cells or fragments of protoplasm, no distinction can be drawn between extension of the individual and multiplication of individuals. And withal combined with these characters of life is, after the manner of their kind, their independence of special environments. Thus, upon their increase follows their dissemination. They are not bound by the conditions of their existence to be local; but they can invade various parts and flourish still. It would appear, then, that much danger lurks in the designation "embryonic" to cancer substance, and that it is of the first importance to beware of this. Malignant growths are heterologous in structure, unlike in this respect any adult tissue. But their substance resembles in physical characters embryonic tissue. It is only

Digitized by Google

on a level with it too, and this is of prime significance, in grade of development. But it contrasts strikingly with it in this—that while the destiny of tissue which is truly embryonic is to a higher form of structure, this, which has no such power, retains in full measure the primitive capacity of reproduction and its comparative indifference to the conditions under which it exists. Although, as we all know, it is not correct to say that the higher animals, in the course of their development, pass through states identical with those of the adult condition of the lower, it is not incorrect to say that the higher animals, in the course of their development, pass through successive stages which in grade correspond to or are on a level with the ultimate stages of the lower. It is thus, and thus only, that we compare cancer substance to embryonic tissue.

This view seems to me to be strengthened by some facts which at first sight may appear to be in direct contradiction to it. Cartilaginous tumours, for example, are homologous structures—that is to say, they resemble generally certain of the normal tissues of the adult body; yet cartilaginous tumours, although usually innocent, occasionally behave, as everyone knows, like malignant growths. They grow with rapidity, and they reappear in distant and various parts. They are indeed singular among tumours in the respect that apparently the same structure will in different cases be endowed with such different attributes. But then it should be remembered that there are two kinds of normal cartilage, distinguished not so much by their structure as by their life history: the one called temporary, the other permanent cartilage. The one form does not throughout its life pass beyond the condition of cartilage; the other passes, sooner or later, into bone. There must therefore be something fundamentally different in the nature of these two forms of cartilage. Now, the enchondromata, which in their nature resemble the former kind, are localised, are innocent. They may be, and often are, multiple, and sometimes grow freely, and this quite accords with the simplicity of their structure. But the enchondromata which in their nature resemble the the latter kind are more or less malignant. They remain on a level only with structures which are fœtal, and with the absence of further development is associated the power of increase and of dissemination. It may be said that the cartilaginous tumours which are innocent show no advance of structure beyond those which tend to malignancy, none indeed that we can yet discover; but then neither do some forms of permanent cartilage differ in this respect from fœtal cartilage, yet we must regard the one as fully formed tissue, and the other as only in a more rudimentary state. In such microscopic structures it is not always practicable to discern the grade of development in the permanent aspect. The grade of a fat cell or of a gland cell must be interpreted rather by the specialisation of its functions than by its obvious structure. And let me observe that this attempt at explanation is not affected by the view we take of the nature of the transformation of cartilage into bone. Whether we regard it as an act of development or of degeneration, whether we regard bone or cartilage as the higher structure, still in the passage from cartilage into bone there is metamorphosis, further change, a tissue still further removed from the embryonic grade. In truth, the relation of cartilage to bone is by no means a peculiar one. Before we can determine to call any change either development or degeneration, we must become clear on the meaning of these terms; but it seems to me that any just view which will lead us to call ossification of cartilage an act of degeneration will lead us also to consider the several stages of the formation of other tissues as acts of degeneration. In this view the germ is the highest of all structures, for of all structures it possesses the greatest capacity for the highest phases of vital action. As we pass from the general to the special this power dies out, and at length there is only the power, and this to a limited extent, of self-maintenance. In the qualities in which cartilage can be said to be above bone all young structures are above adult ones.

I suppose it must be admitted that the present classification of tumours is not altogether a satisfactory one; but it was undoubtedly a great step onward when those tumours which, although not cancer proper, possess some of the worst features of malignancy, and which as a class are distinguished by the obstinacy of their disposition to recur, were brought together into the great group under the title of sarcoma. The title itself is an unfortunate one, but, nevertheless, our knowledge of the subject of tumours becomes clearer if we understand the chief marks of distinction, both pathological and clinical, between cancer and sarcoma, even without reference to the doctrine of their respective origins from epithelial and connective tissue, or rather from structures derived from the epiblast and hypoblast on the one hand, and from tissues derived from the mesoblast on the other. But under the term sarcoma is included a large class which may be very fairly subdivided into orders that for the most part differ strongly from each other; and this must of necessity be so if the view on which I have ventured to insist be well founded, for the sarcomas, in truth, represent the several connecting links which pass between the two extremes of cancer on the one hand, and quite innocent tumours on the other. The worst of the sarcomas are almost or altogether as bad as the worst cancers, and in their structural elements they very closely resemble them. Nay, in some instances they overlap or even pass to the other side. The clinical history of some forms of melanotic sarcoma is far worse than that of some forms of epithelial cancer; while some of the outgrowths which still fall within the class of sarcoma, as, for instance, the common nasal polypus, or myxoma, as it is called, may fairly claim by its behaviour to be ranked amongst tumours which are innocent. And as in the clinical history, so in the structural elements of sarcoma, the same gradation prevails. In this class, we pass through all degrees, from the scarcely altered cell, or fragment of protoplasm, through oval, spindle, and fusiform cells, to the fully formed fibre. These three great classes of tumours, then, are distinguished by the grade of development of the structures which constitute them. Those tumours which are recognised as innocent ones are constituted of elements which, for the most part, are on a level in grade of development with many of the fully formed or adult tissues of the body, and therefore in physical characters they are identical with them. Those tumours which are included in the class sarcoma are constituted of elements of various grades of development, being on a level with the successive stages of formation of some of the normal tissues. And those tumours which form the most malignant cancers are constituted of quite rudimentary elements, those of the lowest grades of development being but on a level with the embryonic stage of normal structures.

With reference, however, to this classification, it must be remembered that some tumours are of what may be called mixed or compound constitution—that is to say, that they consist of different structures in different parts. In some parts they consist of tissues like the mature normal structures, in other parts of more or less rudimentary forms; and, of course, their clinical characters will vary accordingly. Hence, unless an examination of such a tumour is very thorough and complete, any inference drawn from it may be very erroneous. Perhaps most tumours present, in some degree, differences of this kind. But, then, when structures of some low grade of development are discovered the question which is of cardinal importance still remains to be answered, Whether these are on their way to further development, or whether they have already reached their level and live only to multiply and invade? Another point of importance in reference to such a classification is to beware that we do not confound mere shape or form of these structural elements with their nature and attributes or rather to be cautious in drawing any inference of the one from the discovery of the other; for example, epithelioma of the lip and carcinoma of the breast are both composed essentially of what are called cells. But most of the cells of epithelioma are properly so-called. They are more or less mature. But the so-called cells of carcinoma are, as I have said, but fragments of protoplasm, and never reach to the level of true cells. To be sure, the grade of development in each case is low enough, and therefore both kinds of growth are malignant; but still there is a marked difference of grade in the two cases, and therefore an obvious difference in degree of malignancy.

I would venture to insist upon the significance of the fact that the present classification of tumours, which has been gradually worked out as the result of long and patient investigation, but without any reference to the principle I have been endeavouring to set forth, should nevertheless be in such accordance with the laws which govern the phenomena of life in general. It is suggestive enough that two paths of inquiry, separately pursued—that of clinical study and that of histological research—each lead at length to the same conclusion; that different degrees of malignancy of character should correspond with different grades of develop-

Digitized by Google

ment of structure; that in morbid structures, as in normal forms of life, there should be an inverse relation between the capability to increase and extend, and the power of passing, by development, from the general to the special. And in the examination of a tumour, with the view of forecasting its clinical history, it appears to me that this is the chief question which should be taken into consideration. It will assist us less to know that any given tumour belongs to this or that particular class and order than to ascertain its own exact nature from a thorough investigation of its substance. Of course help in this, to a greater or less degree, may be derived from all the circumstances which pertain to it, not only by considering it in reference to the group to which it may belong, but also by reviewing its own previous history. But withal, when corrected or adjusted by such considerations as these, and others, too—such as its situation and mode of growth, and the local and general conditions to which it is subject—the first place may be given to a complete investigation of its anatomy. I say complete investigation, because of the fact already referred to that some tumours are of mixed characters, and their potency for mischief has perhaps to be estimated by the worse rather than by the better parts of them. I think if in a doubtful case I had to depend for prognosis on one source of knowledge only, I should choose to have this: the family and personal history of the patient, his or her own age or period of life, the physical characters of the tumour and its relation to surrounding structures, its place and previous history, especially its rate of growth, and, beyond all, its disposition to affect neighbouring and distant parts. Of course these together, and some of them alone, oftentimes speak clearly enough; and would, and should, with our present knowledge, outweigh any evidence derived from anatomical characters only. But when serious discrepancy occurs, as, indeed, it sometimes does, between clinical and anatomical evidence, this is due, I venture to think, rather to deficient examination or defective interpretation of what is seen than to any fallacy in the principles involved in it.

It is in accordance with our knowledge of the relations of the lowest individuals to the conditions under which they exist that malignant tumours should be very largely influenced by these. Look, for instance, at epithelioma of the tongue. Epithelioma, as a rule, is not reckoned as the most malignant form of cancer, and yet what a terrible history is that of epithelioma of the tongue! And may not this, at least in great part, be explained by its place and the conditions to which it is exposed; to the great vascularity of the tissues among which it lives; to the warmth, moisture, and continual motion; to say nothing of repeated, though perhaps slight, injury and inevitably frequent irritation? Yet, after all, what is the sum of the effect of these causes here upon diseases of a totally different nature? Surely the life history of cancer, as of any normal individual, is determined, in the first place, by its own endowments, which are the outcome of its structure.

Tumours are living structures, distinct outgrowths in some part or other, of the body; local or limited to a particular place in inverse ratio to the capability of their elements to adjustment to different conditions of life. Like the natural structures and organs, they have an independent life of their own, which is more or less influenced, modified, and controlled by the life of the body. Like natural structures, they have an inherent power of maintenance, but this power is regulated by the condition of the body in general. Tumours, by certain members of their class, approach very nearly to normal structures, and, indeed, between some of these and what may be fairly called local hypertrophies of these no well-defined line of demarcation can be drawn. Some of the chronic mammary or glandular tumours illustrate this. But, even in such outgrowths, the first departure from normal type is shown, not only in the formation of their substance, but also in the fact that they are not in such close physiological relation with normal structures as these are with each other. The sympathy which universally prevails between the several structures and organs of the body, and which is maintained either through the blood or by the nervous system, or in both ways, varies in degree among normal structures. But between all these tumours of the lowest organisation is found; they rise and [illegible] with the [illegible] of general life, and they are [illegible] by [illegible] structures. Thus, by the [illegible] and [illegible] and [illegible] and

elements of the organ, or by the development anew of additional elements. The organ may become larger by an increase in the size or in the number of its elementary structures. Thus we have what is called simple hypertrophy, and what is called numerical hypertrophy or hyperplasia; and I think there can be little doubt that increase by hyperplasia is at least the more common process. In many cases this is clearly revealed, as in epithelial structures generally, and glands more particularly. Now, surely, the transition from a local hyperplasia to a distinct tumour is not a very abrupt one. Nay, is it not, I repeat, sometimes very difficult if not impracticable, as in the instance of certain masses in the mammary or prostate gland, to draw any line of distinction between them? The mystery, then, which enshrouds the origin of tumours appears to envelop also other eccentric modes of vital action which are nevertheless more akin to some of the normal processes of life. Before we shall ever be able to answer the question why or how do tumours form, it seems to me that we must be able to solve the problem of normal growth and development, and to answer the question why or how it is that these continue up to a certain point, and then suddenly cease.

Clinical Lectures
ON
CASES OF DIFFICULT DIAGNOSIS.

By SAMUEL FENWICK, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

(*Concluded from p. 990.*)

IT will be remembered that there is a considerable difference in the symptoms in the two cases which occurred in our wards and which I have selected for our consideration. In the first the patient was suddenly attacked with severe pain of the abdomen, which was more or less present until death; whilst in the second scarcely any pain was complained of, and diarrhœa formed the first and the prominent symptom throughout. Then it must be remembered that the perforation occurred in the former case whilst the patient was in perfect health; in the latter it presented itself in a person labouring under chronic phthisis. Now, this distinction holds good when large numbers of cases are examined. I have collected eighty-five cases in which the first symptoms are recorded, and of these sixty-three, or 73 per cent., complained of abdominal pain as having ushered in their illness. The onset of the pain was in almost every case sudden; in thirty-two it was referred to the abdomen generally; and in twenty-one it was located in the right iliac fossa or in the hypochondrium. According to my own experience where abscess only is the result of the perforation the pain is at first confined to the lower portion of the abdomen, and is often of a colicky character; but when general peritonitis is developed from the first the pain is more severe and more generally diffused. In one case the symptoms are recorded as those of "gravel," and I have myself seen frequent and painful micturition form the earliest indication. In two instances the more dangerous symptoms were preceded by tenesmus. In eight well-marked rigors preceded the pain, but this symptom has not fallen under my own notice. Vomiting is recorded as being present in the commencement of the illness in eighteen, having generally shown itself immediately after the pain. Collapse is only noticed in four, showing a striking contrast to the frequency with which it presents itself in perforation of other parts of the gastro-intestinal canal. Constipation was only noticed in eight cases as a primary symptom, probably because the accident so frequently occurs in persons in good health, and in whom the action of the bowels has been regular. Diarrhœa was noticed in nine out of eighty-five, but in almost every case the patient was suffering from phthisis, from typhoid, or some eruptive disorder. In two cases the initial symptoms were so obscure that they are stated to have resembled typhoid fever. If, then, we look again at these figures, we shall see that the most general symptom that ushers in the illness in a person previously healthy is a sudden and severe pain of the abdomen or of the right iliac region, generally attended by vomiting, and in some cases by rigors; but that where it occurs in those suffering from phthisis or typhoid, pain is often slight or altogether absent, and diarrhœa is then the prominent initial symptom.

We found that perforation of the appendix was capable of producing very different effects according as it might lead to adhesion between the injured part and some of the neighbouring organs, or might give rise to general peritonitis or to localised abscess; and it is evident that the symptoms presenting themselves during the life of the patient will vary according to the pathological conditions that may have arisen. We must therefore, in order to obtain an accurate clinical picture of the disease, examine cases of each kind by themselves as far as it is possible to do so. First, then, let us look at the symptoms that present themselves in cases that terminate by adhesion. A man, thirty years of age, was admitted under my care complaining of severe pain in the right iliac region, increased on pressure, vomiting, and obstinate constipation. Four years before he had a similar attack and was ill for three months, but he perfectly recovered, and remained well until two days previous to his admission, when he exerted himself at a game of cricket. On reaching home he began to vomit, and pain of the right side suddenly attacked him. The man died, and we could not obtain a post-mortem; but there seems little doubt from the symptoms and the physical signs that he had perforation of the appendix, and that in his exertion of the abdominal muscles he had ruptured some old adhesions and thus induced peritonitis. There are some similar cases on record, in which rupture of adhesions of the appendix were proved by examination after death to have taken place, and the previous illness had been described as "typhlitis"; so that in all probability the symptoms that present themselves in the cases that terminate in this favourable manner cannot be distinguished from those of inflammation of the cæcum. The occasional occurrence, however, of such cases should lead us to warn patients not to subject themselves to undue exertion for some time after any severe attack of inflammation in this region.

Whenever general peritonitis is excited the symptoms indicative of that condition present themselves, but in many cases they are considerably modified, as in other cases of suppurative inflammation of a serous membrane. Thus it is not unusual for the pain to lessen for a day or two, and the patient to express considerable relief, although the disease may be progressing. In some instances, probably from the appendix becoming surrounded with lymph, the patient appears to be convalescent, when he is again suddenly prostrated by an accession of inflammation induced, we may suppose, by an escape of a portion of the inflammatory products into the peritoneal cavity. A case of this kind came under my notice a short time ago; a gentleman suffered from the usual symptoms and physical signs of perforation of the appendix, from which he gradually recovered; but when apparently convalescent, he was again attacked by illness, and rapidly sank.

Tenderness on pressure is experienced over the whole abdomen, but is always most severe in the right iliac or the hypogastric region. This is the case even when the pain is chiefly referred to the epigastrium, or near the umbilicus, and it often affords a clue to the real seat of the mischief—for instance, a sailor was suddenly attacked with pain in the epigastrium, followed by vomiting, and when admitted under my care he presented the ordinary symptoms of acute peritonitis; but although the abdomen was everywhere tense and tender, it was chiefly so in the region of the cæcum, and after death we found he had perforation of the appendix. The pain, in many instances, radiates downwards, and in five out of sixty-two cases it was chiefly experienced in the right thigh; and in one case it is said to have been felt near the anus. Vomiting generally occurs, and often at an early period; but it is, I think, more readily kept in check by opium than when it accompanies peritonitis arising from other causes. As a rule, constipation is present, but can be relieved by the use of enemata; in twelve cases out of sixty-two diarrhœa was a prominent symptom. You must here bear in mind that we are now speaking of peritonitis produced by perforation in persons previously healthy, for, as we shall shortly see, severe diarrhœa almost always accompanies the disease when it occurs in phthisical individuals. The pulse is usually quick from the first, and remains so, even if the other symptoms seem to be ameliorated. It is worthy also of remark that the temperature is rarely very high, even in non-phthisical cases; and I have

Digitized by Google

known this coolness of the skin lead practitioners to doubt if the case was such a dangerous one as it otherwise appeared. In the last four cases that have occurred at this hospital we find the temperature varied; in one case from 100° to 101°, in the second from 97·6° to 99·8°, in the third from 98° to 99·6°, and in the fourth from 97·5° to 99°. Now, it must be remembered that the disease occurs for the most part in young persons, in whom we should expect any serious inflammation to light up very high fever, and we must be, therefore, on our guard against allowing the coolness of the surface to mislead us as to the gravity of the case. Death always takes place from exhaustion, and is not unfrequently preceded by delirium.

When an abscess only results from the perforation of the appendix the progress of the disease, as well as its duration, greatly differ from those in which it is followed by general peritonitis. We shall see this best by contrasting the following case with those previously related.

CASE 3.—A man, aged twenty, was admitted into my wards complaining of severe pain and swelling of the right side of the abdomen. Six weeks before, when at Newcastle, he was suddenly attacked with pain in the right side, which was at first slight, but gradually increased to such an extent as to compel him to leave his work. Shortly afterwards he noticed a swelling in the right iliac region, which became very hard and increased in size in proportion as the pain became more severe. On examination, a large area of dulness could be made out by percussion occupying nearly the whole of the right side of the abdomen, a swelling also presenting itself in the right lumbar region; it was very tender on pressure, but no fluctuation could be discovered. The temperature was 102·8°; the pulse 136; tongue dry and furred; appetite bad; bowels confined. Four days afterwards he is reported to have been much worse, was in great pain, perspired freely, and the temperature was 101·5°. On the sixth day he was only semi-conscious. Temperature 100°; abdomen greatly distended, and the following morning he died. At the necropsy the appendix was found to have been perforated and communicated with a large abscess. General peritonitis was also present, but seemed to be of recent occurrence.

You will be at once struck with the slow progress of this case as compared with those in which peritonitis had immediately followed the perforation, and you will observe that, on account of its longer duration, there was a more distinct appearance of tumour during life than in the two cases formerly quoted. Of sixteen of the cases I have collected in which an abscess only was present, the existence of a well-marked tumour is mentioned in 40 per cent., but in only 20 per cent. could fluctuation be discovered, and in only six of the sixteen was pain in the abdomen a prominent cause of complaint. We found constipation was generally present where general peritonitis had occurred; but when there is abscess alone diarrhœa is more common, five out of the sixteen having suffered severely from it.

In the case just quoted peritonitis eventually occurred, but in other instances a more favourable result is observed, on account of the abscess bursting externally, or into some of the neighbouring organs. I have before mentioned a case admitted into my wards three years ago, in which an abscess formed on the right thigh, and fæces were evacuated when an opening was made into it; others are recorded in which pus was discharged into the cæcum or into the rectum, as occurred a few years ago in a person admitted into this hospital. In the following case a communication had probably taken place between the appendix and the vagina.

CASE 4.—A lady, about thirty years of age, consulted me on account of very severe attacks of colic, and on examining the abdomen a large scar was observed over the cæcum, which, from the bulging below it, seemed to be adherent to the large intestine. She stated that at the age of twelve she had been suddenly attacked with pain in the right iliac region, which confined her to bed for many months, and which was eventually relieved by the bursting of a large abscess on the site occupied by the scar. Since that period she had also observed a slight discharge of a brown colour from the vagina, and occasionally small seeds presented themselves in it. On examination a minute opening was detected in the upper part of the posterior wall of the vagina, and small particles, evidently of a feculent character, were found. She was relieved of the colic by careful regulation of the bowels, and the opening into the vagina was permanently closed by the application of the galvanic cautery.

It will be remarked that the second case I quoted differed considerably from the first in the very slight amount of pain, the depression of the temperature and the persistence of severe diarrhœa, and that the patient was suffering from chronic phthisis when attacked by the perforation. If therefore we wish to obtain an accurate clinical picture of the disease, we must consider such cases separately, for we shall find that in the invasion and the symptoms they are essentially different from those occurring in healthy individuals. I have collected eight cases of phthisis in which this accident occurred, and in six persistent diarrhœa is mentioned as the prominent symptom. In one there was no suspicion during life that perforation had taken place, in three it is expressly remarked that pain was not complained of, and in three a certain amount of pain was experienced in the lower part of the abdomen, but it was not severe. Tenderness of the hypogastric region is only mentioned in one case. No mention is made of the temperature in any of the above cases, but in Case 2 it will be observed that it was generally below the normal point. The question naturally occurs, Why should there be this difference between the symptoms of the same disease occurring in a phthisical and a healthy individual? In the first place, we must remember that in the former the perforation is produced only by an ulceration, and that therefore no concretion or decomposing material is suddenly introduced into the cavity of the peritoneum, so that time is given for the localisation of the mischief by adhesions to the surrounding structures; and in the second place, inflammation is not so readily lighted up in a person whose strength is reduced by long illness as in one who is in a robust state of health.

With the exception of the few cases in which the appendix becomes adherent, or in which the abscess is discharged into some of the neighbouring organs or bursts externally, death almost always results from perforation of the appendix; but the duration of the disease varies greatly according to the pathological conditions that have been produced by it. Thus of fifty-seven cases the date of whose deaths is recorded, forty, or 70 per cent., died within the first week of illness; eight died in the second week, three in the third week, and the remainder lingered from nine to twenty-one weeks. As regards the deaths in the first week, four died within twenty-four hours of the perforation taking place, six on the second day, four on the third day, five on the fourth, three on the fifth, eleven on the sixth, and seven on the seventh day. All the deaths occurring in the first week were from peritonitis; in the second week four died out of ten cases with abscess only, two died of abscess in the third week, one in the tenth week, and three lived more than thirteen weeks, and eventually died with abscess unaccompanied by peritonitis.

The physical signs presented in cases of perforated appendix vary in different cases, but they are so important that you will scarcely be able to arrive at a correct diagnosis unless you take them into careful consideration. When general peritonitis is present there is, of course, considerable distension of the whole abdomen; but when abscess only exists there may be only a slight fulness in the hypogastric or iliac region, and the rest of the abdomen may present no appearance of enlargement. There is almost always a feeling of increased resistance to pressure in the iliac or hypogastric region, but at an early period you can detect no distinct tumour; when, however, it is a chronic case, an undefined tumour can be usually distinguished in the affected part of the abdomen. It is very rare for fluctuation to be felt on account of the depth at which the pus is situated. Pressure always gives rise to more or less pain, and this is more especially the case when abscess alone is present. In many cases you can detect through the rectum, as in Case 1, a tumour, which is formed by the adhesion of a number of intestinal coils enclosing pus. The percussion note is tympanitic in all parts of the abdomen, but at an early period it is less distinctly so over the site of the abscess. At a later period the dulness becomes more complete, but you should remark that the line of dulness does not alter with the position of the patient, so that you know the exudation is not free in the peritoneal cavity. I have mentioned in Case 1 that percussion over the cæcum elicited a clear note, but it also produced a gurgling sound, as though a cavity filled with air and fluid was situated under the finger. This sign has been observed in other instances, and is likely to be of use in difficult cases, but, unfortunately, it is not always present.

The diagnosis is of course most important, inasmuch as the treatment must be based upon a clear conception of the

Digitized by Google

pathological conditions present in each case. The chief points to be borne in mind are: the suddenness of the attack of severe pain in a person previously in good health, the more or less rapid supervention of peritonitis, the increased tension and tenderness in the right iliac fossa and in the hypogastrium, the diminished resonance on percussion in this region, often attended by a gurgling noise, and in some cases the presence of a tumour in the pelvis, ascertained by an examination made by the rectum. You may easily mistake perforation of the appendix for a number of other acute and chronic diseases.

In intussusception we have, as in perforation of the appendix, sudden attack of severe pain, vomiting, constipation, and tumour of the abdomen; but the pain in the former is more colicky and intermitting, the vomiting and constipation more severe, the tumour is better defined, harder, less tender, and there is almost always either hæmorrhage or the passing of blood and mucus, whilst there is an absence of the tension and tenderness, of dulness and gurgle on percussion in the hypogastrium or right iliac region, as in perforation of the appendix.

In typhlitis you have also pain and tenderness in the right iliac region, together with the presence of a tumour; but it differs from the ordinary cases of perforation of the appendix in its onset being more gradual, in the pain, tenderness, and constitutional disturbance being comparatively trifling, in the absence of frequent vomiting, and in the tumour being well defined. But where perforation has taken place in an appendix situated close to or behind the cæcum, it may be impossible to distinguish between it and ulceration commencing in the cæcum itself. But you should remember that the latter is very rare excepting in phthisical subjects. Judging from my own experience, I should advise that whenever you observe the tumour in a case of typhlitis very slow in disappearing you should suspect perforation of the appendix and watch the case most narrowly.

There is a form of acute tubercular peritonitis, of which you have lately seen an example in our wards, which may be confounded with perforation of the appendix; for you have pain and tenderness of the hypogastrium, dulness on percussion, and fever. In the former the onset of the disease is more gradual; the pain and tenderness are more general; there is no distinct tumour or increased tension in the hypogastrium; if there is dulness on percussion, the line generally varies with the position of the patient; diarrhœa is urgent; and there are, in most cases, some signs of consolidation in the lungs. The absence of tumour in the iliac region or in front of the rectum is, however, the chief point; for, as we have already seen, where perforation occurs in phthisical subjects there is generally very slight pain, and severe diarrhœa is often the only prominent symptom. We have lately had two cases in the wards which might, perhaps, give rise to doubt; one being an instance of inflammation of the connective tissue of the pelvis, the other of retro-uterine hæmatocele. In the first, the patient, a female, had been suddenly attacked with pain in the side, followed by fever and a sense of fulness and great tenderness in the iliac region, with flexure of the thigh upon the pelvis. But, as is most general in such cases, the left side was the seat of the mischief, the symptoms came on after a miscarriage, and, on examination by the vagina, a soft, diffused, painful swelling was discovered to the left of the uterus. An abscess shortly after this formed in the left side and was opened. Such cases would only give rise to doubt, when they occur on the right side, and where, as occasionally happens, the perforation of the appendix produces an abscess around the cæcum, and involves the structures in the iliac fossa; but a careful examination by the vagina and rectum, which should never be neglected, would at once reveal the true nature of the case. In the second case, which was one of hæmatocele, the patient had been suddenly attacked with pain in the abdomen, and on admission a painful swelling was detected on the right side of the hypogastrium. But the symptoms had appeared at the catamenial period, the patient was very anæmic, and on examination by the vagina a large swelling was found blocking up the pelvis, pushing forward the uterus, and compressing the rectum. Such a case could only be confounded with perforation of the appendix by the practitioner neglecting an examination by the vagina. You will probably think it unnecessary to discuss the probability of a disease of the right ovary being mistaken for perforation of the appendix, but the chance of such an error has been mentioned by some authors. The examination by the rectum or vagina would in most cases suffice to settle the question, for the clear, well-defined edge of an enlarged ovary is very unlike the diffused, elastic swelling arising from local peritonitis, and in addition to this the ovarian disease is a chronic malady, the other is acute. Still more unlikely is it that you should confound an enlarged kidney with the disease in question. Renal diseases of this kind are always chronic, the tumours formed by them lie deeply behind the colon, and can be traced backwards to the loin, and the urine contains blood or pus. In one case, however, I met with a renal tumour lying behind the cæcum; but there was little pain or tenderness, no vomiting or constipation, and the urine contained blood.

In the earlier cases of perforation of the appendix placed on record venesection seems to have been generally trusted to as the only means of cure, under the impression that the disease was of a purely inflammatory character. It is scarcely necessary to say that such treatment proved of little benefit, inasmuch as the inflammation was the result of the introduction into the serous sac of a decomposing, or at any rate of an irritating, material which no amount of bloodletting could remove. Its only effect was to lower the vital powers of the patient, and thus to diminish his chance of recovery by adhesion of the injured part to some of the neighbouring organs. Other cases were treated by the use of drastic purgatives, on the supposition that the symptoms resulted from intestinal obstruction; but although in most cases the bowels were readily opened, the fatal termination of the disease was not thereby obviated. On the contrary, the use of aperients proved to be so detrimental that they were entirely abandoned in this as in other forms of peritonitis. Of late years opium has been generally employed, but there has been no diminution in the mortality of the disease. I have prescribed it in every case that has come under my notice for some years, either alone or along with belladonna; it has always relieved the pain, lessened or altogether subdued the vomiting, given sleep, and proved an immense comfort to the patient, but in no single case has it appeared to avert the fatal termination.

Another plan of treatment has, however, been successfully adopted—viz., that of laying open the abscess formed around the perforation and allowing the pus to escape. The earliest case on record is one performed by Mr. Hancock, which ended in the recovery of the patient. Twenty years afterwards Dr. Parker of New York operated upon a case successfully, and Dr. Gordon Ruck of New York has collected thirteen cases of this operation, of which twelve recovered and only one died. I have twice advised this procedure; in the first case it was not performed until the patient was evidently sinking, but pus was found and evacuated; in the second, which was a very chronic one, the abscess was opened and recovery ensued. I have before mentioned that fluctuation can rarely be distinguished in abscesses of this kind, and out of ten recorded by Dr. Ruck it could be felt in only one, proving that there is no necessity to wait until this sign of abscess can be discovered. None of the above cases were operated upon before the seventh day, and, with one exception, the operation was not attempted until between the seventh and the fifteenth day; but we have already seen that forty out of fifty-seven cases died during the first week of illness, so that if the rule should be followed, as has been hitherto laid down, of waiting until the pus is completely localised by adhesions, the operation will be restricted to a very small number of those who are attacked with this formidable malady. Theoretically it would seem to be much better if we could cut down upon the appendix as soon as the diagnosis was tolerably certain, tie it above the seat of the perforation, and remove from its neighbourhood any concretion or decomposing material that might be the cause of irritation. The only objection that I can see to an early operation is that adhesions to the neighbouring organs might be prevented; but when we reflect how very rarely the fortunate termination occurs, and how certainly death follows if it does not take place, we may, I think, dismiss the objection from our consideration. But even when adhesion does result from perforation, the fatal issue is in most cases only postponed, for, as we have before shown, the adhesions are often torn asunder by some undue exertion of the abdominal muscles, and fatal peritonitis ensues.

Two methods of operation have been pursued: in one an incision has been made directly into the suppurating part and the pus at once evacuated; in the other the incision has only been carried down to the fascia, and either the pus has

Digitized by Google

been allowed afterwards to escape spontaneously or an aspirator has been passed into the most depending portion of the swelling and the contents thus evacuated. It is evident, however, that if an operation were performed at an early period the incision must be carried down directly to the injured part; for we cannot suppose that pus would be formed and localised until many days after the perforation had taken place.

The choice of the method of operation must of course be left to the discretion of the surgeon, and will probably require to be varied according to the circumstances of each case. Of one thing we may be quite certain, that no drugs are likely to be of much avail; for your common sense will tell you that when you have an irritating material suddenly introduced into a large serous sac the only chance of giving relief is to remove it, and thus put a stop to the original cause of the mischief. The office of the physician, therefore, will most likely become restricted to diagnosis, and it is only by carefully watching the first symptoms and the physical signs of the disease and by comparing them with those of other disorders that may simulate it, that we shall be able to arrive at such a correct judgment as may justify the employment of surgical measures at an early period of the case.

CHOLERA.

BY MAX VON PETTENKOFER, M.D.,
OF MUNICH.

(*Continued from page 994.*)

I DO not doubt that instances may exceptionally be found amongst infectious diseases in which the behaviour is essentially the same as that of cholera on the ships going between Europe and New York. But the question is, How do such cases generally, not exceptionally, behave? Vaccinated persons may be brought into contact with cases of small-pox without fear of infection; and at times, individuals who have not been vaccinated may come in contact with small-pox without taking the disease. As a rule, however, small-pox on board ship behaves very differently from cholera. We shall pass in review an instance of a severe epidemic of cholera on board ship, notwithstanding that it favours the views and theories of the contagionists. The following specimen is chosen, for the reason that it occurred on a man-of-war, and as there are many such vessels the advantage of comparison exists. The *Britannia* was in the spring of 1852 equipped as an admiral's ship, and was generally stationed off Malta for the first year; in August, 1853, it went to Besika Bay, and in October to Constantinople, where it remained the whole winter; and, after the declaration of war, went in March, 1854, to Varna. With the exception of a brief expedition to Odessa and Sebastopol, it remained at Varna all through the summer. In August cholera broke out, and first of all amongst the troops on shore. The ship and the whole fleet were up to this time perfectly healthy. It was believed that the French had brought the cholera with them from the Dobrudscha, whence some regiments had been sent from Varna. A few of these returned, but the majority met with their death either from cholera, typhus, or marsh fever in the low country of the Donau. After the cholera had begun to subside on land it appeared in the fleet, amongst which it was, however, unequally distributed. At Varna there were assembled fifty-four ships of the line, belonging to the English, French, and Turkish fleets, without reckoning the smaller craft. The *Britannia* lay on August 20th in the bay of Cavarna, fifteen miles by water from Varna. About 100 paces from it were lying two other English three-deckers, the *Trafalgar* and *Queen*, both, like the *Britannia*, manned by 1040 sailors. The *Britannia* lost 139 from cholera, the *Queen* and *Trafalgar* 4 and 6 respectively. On the French and Turkish ships it was the same. Strange to say, the French admiral's ship, the *Ville de Paris*, like the *Britannia*, was most numerously affected; there were 162 deaths, of which 3 were of officers. During the disease the French vessel lay at anchor off the coast with the rest of the fleet. The *Britannia* went to sea in the delusive hope of staying the course of the disease. That cholera should rage on the *Britannia* without causing the death of, or even attacking, one of the sixty officers on board is for the contagionists an inexplicable circumstance. We must now inquire into the reason why cholera was so rife on the *Britannia* whilst the *Trafalgar* and the *Queen* were so mildly attacked. If the outbreak were due to the presence of cases of cholera, or to the linen from cases of cholera, on the ship, it might be urged that this circumstance was common to all the ships. Dr. Milroy has attempted to explain the epidemic on the notion that it was not due to the specific infective material, but to the individual predisposition to cholera. In the night it was found necessary, on account of the cases of diarrhœa and cholera, to close the hatchways on the lower decks while the ship was at sea. Dr. Milroy says: "The men appeared to be poisoned by the foul air which they had to breathe at night.....A more striking example of the deadly effects of impure air during the period of an epidemic, and of the most infallible means to check the evil, cannot be imagined. The immunity of the officers was, on this occasion, unquestionably due to the greater space for breathing purposes which the officers enjoyed." That is an explanation which must satisfy the practical physician. I also believe that impure air is harmful, but I do not think impurity of air sufficient to explain such an explosion of cholera as that above referred to. It must not be forgotten that the *Britannia* went to sea on account of the general poverty of its hygiene. We ought to inquire into the condition of other ships also attacked with cholera, but in which the hatchways of the lower decks were not shut. My witness, who was on board the *Britannia*, assured me that the air was by no means so impure as Dr. Milroy made out. Another mistaken notion which I had taken up was also set right. I thought hitherto that the closing of the hatchways of the lower decks was occasioned by the stormy weather. On this point my informant writes to me thus: "The matter was not quite as you seemed to have imagined, and it will perhaps be best if I give a brief description of what actually took place. The day following our departure from Cavarna Bay a calm overtook us, and instead of the desired cool breeze a burning sun poured down on our sick ship. Then there came a swell on the waters, but no wind. In consequence the ship was so violently tossed that the hatchways of the lowest deck where the crew slept had to be closed, and then followed the worst night, during which fifty-eight men died, a night without wind and without the slightest movement of the superheated air. Nothing was said of a storm. If we had but had one! That the shutting of the hatchways had any influence I do not believe; for owing to the heat the men were allowed to lie about where they pleased, and most of them betook themselves to the uppermost deck in the free air and slept on the floor. The physicians had consented to this arrangement, and under the canopy of heaven the bulk of the fatal cases occurred. In this connexion it must also be observed that the *Ville de Paris*, which did not go to sea, yet suffered as much as we did, in spite of the fact that the hatchways were not shut." So much for the explanation which regarded the shutting of the hatchways and the impurity of the air as the cause of the epidemic. The view of the contagionists meets with no better fate. That a cholera patient should arrive on board with his stools or soiled linen explains nothing, since this circumstance was common to many other vessels without being followed by such consequences. If the infective material were brought in the food and drink on to the *Britannia*, how is that only the crew and not the officers suffered? On this point my informant says: "Provisions came daily from the shore, even during the time we were fifteen miles away, but the officers ate the same meat, the same vegetables and fruit as the crew. The only difference was that the crew drank rum-and-water, whilst the officers had wine." Thus in the drinking water no difference obtained. Ballast might have been a vehicle of infection, and for this purpose sea sand and shingles, and other material, were taken from the shore. But I have been informed "that on the *Britannia*, as well as other English men-of-war, the ballast consisted only of so-called pig-iron, four-sided pieces, which were wedged together in the lowest part of the vessel, and never touched." We have yet to consider the different habits of the men and the officers while on shore before the outbreak of the epidemic. On this matter my informant writes:—"The sufferers, not only of the *Britannia*, but of the rest of the ships of the fleet, had frequent communication by daily visits with the shore as we lay off Varna, and the crew without doubt betook themselves to those poisonous liquors, and still worse places of pleasure, which had sprung up on shore

Digitized by Google

like mushrooms." It may be understood that the company of one ship would, like men of the same regiment, visit places of pleasure together and imbibe the same drink, and so it might happen that a particular crew visited a certain place where cholera prevailed, whilst other crews might have unconsciously kept clear of the places from which it is supposed cholera was taken. It remains doubtful whether the infection was derived through the air, water, or food. If these circumstances be viewed in an unprejudiced light, it will be seen that local conditions may account for the infection and spread of cholera on board ships. On emigrant ships the matter cannot be otherwise, and it is necessary therefore to inquire into the previous history of those who were taken ill on board. I have shown that the eleven cases of cholera which occurred on the *Westphalia*, bound for New York from Hamburg, came exclusively from two German families, and that an epidemic as vast as that which befell the crew of the *Britannia* might be explained if we supposed that a majority of it came from the same district or were placed under the same conditions as the two German families prior to their going on board. The exceptional outbreaks on emigrant ships prove that such an occurrence is possible. That the *Britannia* as a ship was not a place of infection is shown by the freedom from cholera enjoyed by the sixty officers. These points may possibly be cleared up by the appointment of a commission to inquire into the presence and etiological factors of cholera on board ship during epidemics of cholera. Koch has spoken of the occurrence of cholera on ships, and has attempted to reconcile matters on the basis of his doctrines of contagion. He has studied those ships which ply between North America and Calcutta. This line has not escaped my attention, and I have stated the main facts in my paper on "Cholera in India," 1871. Koch comes to the same conclusions as I did. Of 222 vessels which made the voyage during ten years cases of cholera only appeared on thirty-three ships, although they started from a district where cholera is endemic. It appeared to Koch only to be of importance that cases of cholera continued to occur more than twenty days on sixteen ships; therefore these cases could not have originated at Calcutta, but must have been derived from infective material on board ship. If cholera is acquired from the infective material on board ship, how is it that the infective matter is, as a rule, so ineffective and acts only exceptionally? If cholera lasts more than twenty days on board ship, then there must be other causes than those which prevail on land. Let it be assumed that the infective material proceeding from human beings can call forth the disease after the third day and up to the twentieth day. Now, cases of cholera have occurred on board ship as long as forty days after leaving port, of which fact I could give many examples. But these are very exceptional. May it not be assumed that in such cases the infective material might be brought on board and kept effective in some form or other, and that individuals might constantly come in contact with the infecting agent? For exceptional circumstances exceptional causes must be assumed. Properly considered, it will be found that cholera behaves on ships pretty much the same as ague does. When ships leave a malarious district cases of ague occur on board, but when further out at sea they cease to occur. As a rule the illnesses happen only in those individuals who come from shore, though exceptionally the disease shows itself in individuals who have never been ashore. But epidemics of ague have occurred on ships, as Hirsch has recorded in his work on "Malariakrankheiten," where the infection of the crew on shore appears to have been quite impossible, as on a ship which went from an Eastern seaport to England, and yet no one has ventured to say that ague is not dependent on the soil, or that it spreads on ships by contagion from man to man where the people have not been infected on land. The sweat of the sufferers from ague may be likened unto the stools of cholera patients. If the infectious disease, ague, were as dangerous as cholera, it is not unlikely that many more observations on contagion from cases of fever, and on the presence of ague on ships, would have been made and recorded. Any exceptional occurrence in the way of ague on ships would almost certainly be more likely to be recorded if they happened on men-of-war or emigrant ships than if they occurred on merchantmen, on the ground that the rare event is witnessed by a large number of men, and because the state of health of men-of-war and emigrant ships is more carefully registered than is the case with smaller vessels.

(*To be concluded.*)

THE EXTINCTION OF CHOLERA EPIDEMICS IN FORT WILLIAM.

BY A. C. C. DE RENZY, C.B.,
DEPUTY SURGEON-GENERAL, BENGAL ARMY.

PROFESSOR PETTENKOFER, in his paper published in THE LANCET of Nov. 22nd, page 904, writes as follows:—"Koch was further strengthened in his views from the fact that after Fort William was supplied with water no more cases of cholera occurred there, although it had formerly been ravaged by the disease. The gentlemen in Calcutta, however, had not told Koch the whole truth. It was a fact that cholera had begun to decrease in Fort William since 1863, and yet the fresh water-supply was introduced as late as March 25th, 1873." A statement substantially similar to this is made by Deputy Surgeon-General Marston, in his letter published in THE LANCET of Sept. 20th, page 520. In a paper which I read last year before the Epidemiological Society, I referred to the case of Fort William as confirming, with almost the completeness of a demonstration, the opinion long held in this country that somehow or other cholera is mainly communicated through the medium of water. The opponents of this view now find it necessary to deal with this case, and their method of doing so is shown in the extract already given. It is impossible to deny the fact that Fort William was ravaged with cholera at short intervals for upwards of a century, and that for the last eighteen years the disease has abated to such an extent that though it was rarely entirely absent, it has never assumed an epidemic character. Fort William was formerly one of the most unhealthy stations in India. The death-rate of the British troops for a long series of years as given by the Royal Commission on the Sanitary State of the Army in India was 68·96 per 1000, and for the ten years ending in 1856 it was 102·35 per 1000; in the eighteen years ending in 1882 it was only 12·35 per 1000. This extraordinary transformation will appear more striking if it be remembered that during the latter period cholera has again and again prevailed with terrible virulence in the villages in close proximity to the fort, and also in many parts of Calcutta itself. I think it of great public importance that the facts of this case should be placed clearly and indisputably on record. Professor Pettenkofer says that while the cholera in the fort had begun to decrease in 1863 the fresh water-supply was only introduced in 1873, and therefore the two events could not have been related as cause and effect. But the Professor seems quite unaware of the fact that changes in the water-supply began even earlier than 1863, that they had been carried out to very considerable completeness by 1865, and that in 1872 the existing state of things was attained when the Calcutta municipal water was laid on in pipes all over the fort.

I now propose to show by extracts from official reports what was the state of the water-supply in the time of the cholera epidemics, and what were the subsequent changes made in it in the period corresponding to the cessation of the epidemics.

In the appendix to the Report of the Royal Commission on the Indian Army (1860), page 10, the water-supply of the fort at that time is thus described:—"11. The water used for drinking is brought from a large tank on the glacis by native water-carriers. The tank is filled by surface drainage; it is kept perfectly clean, and is *generally* free from foul drainage surface impurities. From the well-known careless habits of 'bhistis' (water-carriers) and native servants, it may not be unfairly assumed that water is sometimes taken from nearer and impurer sources of supply in the ditch." In connexion with this last remark, it must be borne in mind that all the water required for the use of the troops had to be conveyed, in many cases to a considerable distance, by human labour, in leather skins, and that consequently the temptation to resort to a near source of supply was very strong. The ditch-water was largely tainted with the sewage of the fort; it was the most convenient for use, and it was not submitted to filtration of any kind.

The improvements contemplated are thus described in the Royal Commission Report (par. 12):—"The supply of water available for the station is sufficient for drinking and washing, but not for bathing. In consequence the Fort William Special Committee have recommended a steam pump for the purpose of bringing into the fort from the river a due supply

Digitized by Google

of water for all purposes. The number of gallons was fixed at 30 per head, and provision was to be made for filtering 90,000 gallons. The river being unsuitable for six weeks annually, masonry tanks within the fort, having a storage space for two months' supply of pure water for drinking and culinary purposes, have been recommended." Such was the plan proposed, but a different one was adopted. The rainfall on the "maidan" or plane in front of the fort was collected by means of a system of surface drains into two tanks situated at the foot of the glacis.

Dr. Macnamara, the well-known chemist, who took such a distinguished part in urging the importance of improving the water-supply of Calcutta, in his report on the analysis of potable waters, describes the fort supply as follows:—"The tanks are large, and well kept and guarded. Between the tanks is a masonry cistern, which on the opening of sluice-gates can be connected with both or either tank, but before entering the cistern the water has to pass through a considerable thickness of sand and broken brick. From the cistern the water is raised by means of a pump worked by a steam engine to a cistern on the ramparts, and is thence distributed to the stand-pipes placed about the fort. In order to raise water to the level of the upper storeys of the barracks, it is during a part of the day forced up to a lofty syphon-pipe, the level of which is above the level of the barracks." This system, which took some time to carry out, was completed in 1865.[1] Dr. Macnamara, in speaking of the results of his analysis of the water, says, "The dissolved organic matter in the tanks is small in amount, and the water is evidently improving. In September, 1866, a gallon of the water held in solution 13·7 grains of inorganic matter. This September [1867] I found that quantity reduced to 7·7 grains. The water was refiltered in the barracks through the old style of filter. Great attention was paid to the filtering during the time the 3rd Brigade of Rifles garrisoned the fort, and the filtered water was always when I examined it physically good, but the filters added slightly to the amount of the oxidisable organic matter."

In 1868 there appears to have been found a marked deterioration in the water of one of the tanks. Dr. Palmer, the analyst, in his report says, "The water of both tanks having been collected under precisely similar circumstances from the same gathering ground, it would be supposed that the examination of each would be attended with similar results. While, however, the water of the old tank yielded 170 grains of impurity per million, that of the new tank contained 260. The greater impurity in the latter case arose from the presence of soluble materials in the newly dug soil, and that much of this material had its origin in decayed animal matter is proved by the great excess of nitrates and chlorides found in the water." Dr. Macnamara also, in writing of this year, says, "There can be no doubt that the water of the tanks which supply Fort William needs, especially during the continuance of the rains, very efficient filtration to render it thoroughly wholesome. The present filters of sand and broken brick are insufficient, for the water of the stand-pipes in the fort is at all times far from being transparent. The filters, too, altogether failed during the rains." After this the filtering process appears to have improved greatly, for whereas in 1868 the water contained 1·6 per million of albuminoid matter, the proportion ranged subsequently between 0 31 and 0 88 per million.

From what has been stated it will have been seen that during the period of the prevalence of cholera epidemics the water-supply was subject to very little supervision, that it was taken from very dangerous sources, and distributed in a barbarous way. By 1866 the supply had been placed under strict supervision and control. Elaborate arrangements had been made to secure the tanks from pollution, and although the results had not been as satisfactory as was desirable, the standard of purity was immeasurably higher than it had been in the epidemic era. Such being the facts of the case, it appears surprising to me that a man like Deputy Surgeon-General Marston, who had ample means of making himself acquainted with them, could imagine that the question of the improvement in the health of the garrison being the effect of the improvement of the water-supply was to be disposed of by saying that an Order in Council exists refusing to sanction the introduction of the municipal water, and that the health of the garrison had been good for some years before that water was brought into the fort. He altogether ignores the improvements that had been in progress for at least seven years in the source of supply, in filtration, and the system of distribution. It is quite true that the Order in Council referred to was issued. As the introduction of the purer municipal water involved an outlay of Rs. 15,000 for fittings, and an annual charge of Rs. 23,000, the Sanitary Commissioner advised the Government not to sanction it, but wiser counsels afterwards prevailed. To ensure the efficient working of the old system, unremitting vigilance was indispensable, and it was seen to be safer that the fort should be supplied with municipal water, the purity of which was guaranteed by the supervision of highly trained officers exclusively occupied with that particular duty.

As Professor Pettenkofer finds it difficult to surrender the opinions he has so long advocated with such ability, he tries to discover an explanation of the cessation of the epidemics in Fort William in some other condition than the improvement of the water-supply. In continuation of the passage I have quoted from his paper, he says, "Moreover, it was not true that the only improvement effected was the water-supply, for many other changes were carried out, the fortress being made a model of cleanliness. Alterations in the drainage of the soil were effected in and around the foundations of the buildings, which was before nothing but a morass during the rainy season." Now there can be no doubt that there has been great improvement in surface cleanliness since the epidemic era, but there has been the same improvement in other stations without any corresponding change in the prevalence of cholera. I challenge Deputy Surgeon-General Marston, who knows India well, to say whether Fort William is a bit cleaner than Mianmir, Lucknow, Fyzabad, and other stations which are notorious for cholera. For many years the stations of Upper India have been models of cleanliness, but in spite of this they frequently suffer terribly from cholera.

Then as to the alterations in drainage, I do not know on what authority Pettenkofer writes. All I know is that in the long series of reports by the Sanitary Commission, extending from 1864 downwards, no mention is made of such works. A drain may have been cleared out here and there, but no subsoil drainage of any kind was carried out, nor was any such scheme proposed by the committee which drew up the replies to the queries of the Royal Commission. The fact is, there are insurmountable difficulties in the way of drainage owing to the lowness of the site, which is only one foot above the mean level of high water of the Hooghly during the rains. The site is surrounded by rice fields and vast swamps which it is utterly impossible to drain. It was to these swamps, which remain to-day as they were thirty years ago, that the committee referred to attributed the malarious influences that affected the troops in the fort. But there is striking proof that the cessation of cholera epidemics among the British troops was not due to any alterations in drainage, for in 1866 the native troops, who had not at the time overcome the prejudice against pipe water, lost 26 per 1000 of strength from cholera, while the British troops lost only 2·0 per 1000; and in 1869, again, the native troops lost 4·8 per 1000, while the British troops entirely escaped. Since the native troops have taken to the use of the new water they have shared in the improvement in health which has been so conspicuous in their British comrades. Moreover, cholera occurs in a most distinctive form at stations where the soil is singularly free from moisture. I instance the case of the Peshawar cantonment, so notorious for cholera, and where the subsoil is perfectly dry to a depth of 100 ft. from the surface. Anyone who knows Mianmir, too, will see the absurdity of attributing the terrible epidemics which have visited that station to defective drainage. The subsoil is so utterly devoid of moisture that no trees can be got to grow without abundant artificial irrigation. On the other hand, Fort William is now free from epidemic cholera, in spite of bad drainage and in spite of being hedged in on all sides by villages that are never free from cholera. The troops have free access to those villages, and there are few years in which two or three cases of cholera do not occur among them, but the disease is no longer capable of assuming epidemic proportions. For upwards of a century the fort was scourged with cholera; for the last eight years it has suffered very little, while during the same period other stations quite as cleanly and with better barracks, better drainage, and an infinitely better climate, have suffered severely. How is this fact to be explained? It is due, in my opinion, to the fact that the fort has had a fairly good water-supply, while in the other stations of Upper India the supply is taken from sources exposed to innu-

[1] Vide Report of the Sanitary Commission for 1865.

Digitized by Google

merable contaminations, and is distributed in a barbarous fashion, which would render a water taken from a pure source dangerous for use. Being fully acquainted with the sanitary condition of every station in the Punjab, I feel confident in stating that no epidemic of cholera has occurred at any place in that province where the water-supply was even moderately good. I am aware that statements contrary to this have been often made in official reports, but I could, if necessary, give details and descriptions of the water-supply in each case that would amply corroborate my assertion. Bad water is a condition common to all the places infested with cholera, however widely they may differ as regards soil, climate, drainage, elevation, or other sanitary conditions.

In the late Afghan campaign the water-supply arrangements could hardly have been worse if they had been specially designed to favour the propagation of a water-borne disease, and to that and that alone the terrible losses of the troops from cholera are attributable. In view to the prevention of such calamities in future, I would strongly urge that the case of Fort William should be investigated by an independent Commission, whose report would carry weight with the Government

Years.	Death-rate per 1000 from cholera.	Death-rate from all causes, cholera included.	Remarks.
A long series of years, as given by the Royal Commission	—	68·96	—
Ten years ending in 1856	—	102·35	—
1859	6·87	25·94	—

and the public. I believe the case is full of instruction as to the measures necessary for the prevention of cholera epidemics. In many up-country stations the death-rate of British troops has in recent years been as high as 70 per 1000, and in some it has been as high as 100 per 1000; while in the eighteen years between 1865, when the water-supply was reformed in Fort William, and 1882, the latest year for which returns are available, the average death-rate of that station was only 12·35 per 1000. What has been accomplished in Fort William might surely be effected in the healthier stations of Northern India. Nor does the case of Fort William stand alone. At Bombay, Nagpur, and in the European quarter of Calcutta there has been a marked decrease in the prevalence of cholera following closely on the improvement of the water-supply. It is most desirable that it should be authoritatively settled how far those phenomena are related as cause and effect. My firm belief is that with a well-managed water-supply the British troops all over India would be *almost entirely free* from cholera, and would have very nearly as low a death-rate as the troops quartered in the United Kingdom. The above table shows the death-rate amongst the British troops in Fort William previously to and subsequently to the improvement of the water-supply.

AN UNUSUALLY SEVERE CASE OF

SYPHILIS ACQUIRED WITHOUT ANY PRIMARY SORE.

BY STENSON HOOKER, L.R.C.P., &c.

THE subject of the following case, whom I will call A. B——, is a medical man, aged thirty, practising in a small country town where cases of acquired syphilis are anything but common.

A. B—— has always led a strictly sober and chaste life. He was in his usual health in February last, when a gentleman's servant presented himself at the surgery to be treated for a thin, watery discharge from the urethra and nocturnal emissions. There was a very insignificant sore under the glans penis, so small indeed that it could only be called an excoriation. A. B—— examined this carefully, and resolved to leave it to take care of itself, the result being that it healed up in a fortnight. The other symptoms were treated, but not syphilitically, and the patient so far improved that towards the end of the month he ceased to attend. In about seven weeks after this, A. B—— began to suffer from very severe frontal headache, both night and day, but worse at night. This increased in severity, and soon partook of a constant stabbing, lancinating character. It was thought that he needed rest and change. No idea of the real nature of the case was as yet suspected. Had he had a scratch on the finger, to say nothing of a sore, the true cause of the pain would probably have been divined; but he emphatically avers (and the averment may be implicitly relied upon) that for some years past he has not had any lesion of the skin in any part of the body, and has run no chance of being syphilitically infected excepting by the servant mentioned above. He now went to the seaside, and a few days afterwards general periostitis of the skull set in, and was so aggravated that the whole head was a mass of nodes of the size of walnuts, the pain being most excruciating. At this time he was closely questioned by a medical friend as to any possible way whereby his system might have been poisoned with syphilitic virus; but after what has been said I need scarcely add that the malady could not be traced to a primary sore. General cervical cellulitis appeared next, with great enlargement of the post-cervical glands; there was now also (about six weeks after the commencement of the headaches) a lichenous rash which covered in a uniform mass the whole of the trunk and extremities; simultaneously with this the tonsils were badly ulcerated, and it was not till then that A. B—— could be got to acknowledge that he was suffering from many of the symptoms of that protean disease syphilis. Iodide of potassium was now taken vigorously, and the pain gradually abated. He was at this time returning to his work, and on his way consulted in London one of the greatest authorities on this particular disease, the throat being still ulcerated, and the rash only beginning to fade. This gentleman told him that there was not the slightest doubt as to the nature of the malady, and carefully examined him for evidence as to primary sore, but none, of course, could be detected. Mercury-with-chalk pills were ordered, and under this treatment the throat rapidly improved and the rash disappeared by desquamation; but for the next twelve months A. B—— suffered from deep fissures and recurrent ulcerations of the tongue, with congestion of the ciliary vessels of the eye, and loss of hair.

Now I can most conscientiously aver that this medical man presented himself as a sad example of one in whom, in spite of all his symptoms, there had never been any primary affection; through what particular channel the poison was absorbed is still, and must as far as I can see, remain a complete mystery; that he never had a chancre I can again most positively aver. A. B——'s patient, it should be said, returned for treatment, this time suffering from the same unmistakable syphilitic symptoms.

Midhurst.

AT Bow-street Police-court, on the 4th inst., Dr. John Cran was charged with a contravention of the Act for the Regulation of the Care and Treatment of Lunatics by unlawfully receiving two or more lunatics in his house without procuring the necessary licence. The case was adjourned.

A DEMONSTRATING VAGINAL SPECULUM.

BY H. MACNAUGHTON JONES, M.D. &c.,
EXAMINER IN OBSTETRICS, ROYAL UNIVERSITY OF IRELAND, ETC.

THE desirability of having such a speculum as would enable the surgeon to demonstrate to a student or students the os uteri and infra-vaginal cervix, in a different manner from that now adopted, and without exposure of the patient, often struck me in hospital work. By such an appliance as that made for me by Messrs. Maw, Son, and Thompson, this can be perfectly achieved. The drawing (Fig. 1) shows the

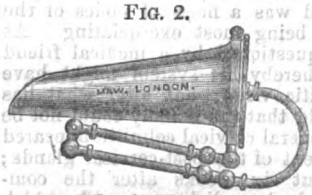

FIG. 1.

One-fourth size.

appliance attached to a speculum. It consists of a nickel-plated steel bracket with three joints, as shown in the figure, which are so constructed as to enable the mirror to be placed at any angle or plane to the orifice of the speculum, from which it is twenty-five centimetres distant. A ring with a groove receives the mouth of the speculum, and will fit any large-sized speculum. The ring is clamped by means of a screw. (This clamp I am having improved.) But this may be so arranged that any sized ring can be applied so as to embrace a smaller speculum. At the other end of the bracket is a mirror, which works in a universal joint. It is three inches in diameter. If it be wished to get a magnified image, a slightly concave mirror can be attached. The entire appliance is shown folded in Fig. 2. It fits into a leather case, and is quite portable.

FIG. 2.

One-fourth size.

By means of this instrument the lips of the os uteri can be seen, either by sunlight or artificial light, several feet away. The patient need not be in the least exposed during the demonstration. The teacher having introduced the speculum and having caught the reflection of the uterus at the plane required, turns the mirror so that anyone standing behind him or at the side, and looking into it, can see both the os uteri or any application which is made to it. It is not necessary to expose more than the orifice of the speculum.

Harley-street, W.

ON NERVI, NEAR GENOA, AS A WINTER HEALTH RESORT.[1]

BY EDWARD HAUGHTON, M.D., B.A., &c.

NERVI is situated about seven miles and a half east of Genoa, just at the head of the gulf, and is well sheltered on the north and east against cold winds. In Cook's Guide to the Riviera it is spoken of as having "come into repute recently as a winter residence owing to its mild climate and sheltered position." It is also briefly described by Dr. C. T. Williams, in his "Climate of the South of France," in the following words: "Nervi, on the Eastern Riviera, about an hour's drive from Genoa, stands on a ledge of level ground which descends in rocky masses into the Mediterranean, here affording boating, bathing, and tolerable fishing. The place is well sheltered to the north and east by wooded hills, on whose sunny slopes the orange and lemon flourish. Olive-groves besprinkled with villas and picturesque hamlets rise about the village, and the view from this spot of the Bay of Genoa and the Col de Tende range is exceedingly beautiful. A good hotel and boarding-house (Hôtel d'Angleterre) with well-sheltered grounds, pleasant walks and rides, and its short distance from Genoa, render Nervi attractive to invalids, many of whom have safely wintered here."

For some unexplained reason the number of English visitors seems to have diminished, and their place to have been supplied by Germans, the proprietors of several of the hotels and boarding-houses being of that nationality.

Not being satisfied with getting accounts at second-hand about the climate and capabilities of Nervi, I determined to pay a personal visit to the place, which I did about the middle of last February, leaving snow and sleet behind me in Basle and Lucerne and several of the northern Italian cities. I also made a point of visiting Pegli on the same day, and then returning to sleep at my hotel in Genoa, so as to make a really satisfactory comparison of the amount of shelter from cold winds afforded by the three localities respectively. The result was that the wind, which was bitterly cold at Genoa, was much milder at Pegli, especially in the valley behind the town, whilst it was perfectly calm and even warm at Nervi, so long as the headlands which protect the place were not rounded by the visitor, who literally has a haven of refuge there, which he should remain within so long as the wind blows persistently from the north or east. It is probable that Nervi remains, so to speak, in an undeveloped state as a health resort from one or two causes which are not likely to be permanent. In the first place, the through traffic to and from Rome goes past it without stopping, or at inconvenient hours for alighting, and the sanitary arrangements of the place, although it has been hitherto absolutely free from epidemics, will need a little overhauling before they are quite agreeable to noses and eyes polite.

The scenery of Nervi is in some parts beautiful in the extreme. As for instance, if we climb the hill at the back of the town and look down on the valley beneath, or stroll along the sea shore, and listen to the murmuring of the waves amongst the rocks, which are here permitted to retain some of the wildness which constitutes one of the principal charms of the neighbourhood. It is to be regretted that the principle of *laissez-faire* is carried so far as to permit strangers to be annoyed by lazy mendicants, and to allow all kinds of refuse to lie about exposed to the sun amidst the very loveliest part of the walk by the sea shore. Various circumstances have convinced me that a bright future lies in store for this pretty watering-place; and I hope, when sanitary zeal is really developed amongst its population, that its authorities may not copy too exactly or servilely the methods adopted in other fashionable localities. Warnings abound on every hand against such a course. First, we have sporadic cases of typhoid at Cannes, then an actual epidemic at Nice, just in the midst of an International Exhibition, and after an immense expenditure of money on "drainage" in both localities. It seems as though many engineers disbelieve altogether in the use of traps of the good old-fashioned S-shape; whilst almost all are afflicted with the superstition that it is only necessary to convey solid refuse into the sea, or even into a lake, in order effectually to get rid of it for ever. It is true that the shores of the British Islands are daily washed by a strong tide which dilutes, if it does not always remove, the more noxious and offensive refuse which we continually pour into it. But to attempt to carry out the same idea on the shores of a Swiss lake, or even the Mediterranean sea, is likely to lead to more lamentable consequences than would be believed if we did not see them actually taking place. There is abundant and unimpeachable testimony as to the horrible accumulation of sewage of the most offensive character in and around the harbours of both Toulon and Marseilles, the very places which are now (August, 1884) enduring the scourge of cholera, and which will probably act as centres whence this vile result of inhaling concentrated filth will be propagated over a large portion of France, and possibly even of Europe at large. Some of the most fashionable of the resorts of the Western Riviera have adopted wrong methods of disposing of their sewage; and it is only a question of time how long their popularity can possibly last. They are also intolerably dear, and treat the unhappy valetudinarian as though he were their natural prey. Are we to be accused of fickleness if we respectfully decline to be fleeced? Those places which give the best value may reasonably expect the most custom, and there is no good reason why accommodation of a very excellent kind, with

[1] Read at the last meeting of the British Medical Association in the Public Health Section, August, 1884.

Digitized by Google

sea-bathing in a mild climate and charming scenery, should not be accessible within forty-eight hours to all who are willing to endure a couple of hours' sea passage between Dover and Calais. The train service is good, and there is no reason in the nature of things why the expense of living at Nervi on good wholesome diet should exceed the cost of London living to the great majority of invalids.

I will not give a list of diseases for which I consider the climate adapted, but content myself with saying that nervous and dyspeptic cases are likely to be quite as much benefited as those in which the chest is affected; whilst in kidney affections the best results have been obtained without any special regimen, and without the alternative of unlimited swallowing of nauseous mineral waters.

ST. BARTHOLOMEW'S HOSPITAL.

CASE OF SPINAL CONCUSSION, WITH PROBABLE FRACTURE OF THE CERVICAL SPINE; RECOVERY; REMARKS.

(Under the care of Mr. THOMAS SMITH.)

FOR the following notes we are indebted to Mr. Alfred G. Francis. See THE LANCET, July 5th, 1884, for two cases under the care of Mr. Bryant at Guy's Hospital.

Richard D——, aged twenty, a waiter, was admitted on June 1st, 1883, into Rahere ward. He was with some friends at a swimming-bath, and dived from a distance of seven feet off a spring-board into the bath, which was seven feet deep at that spot. According to his own account he struck the vertex of his head violently against the bottom of the bath in the region of the fronto-parietal suture, and immediately lost all control over his limbs. He was lifted out of the bath by his companions, who dressed him and conveyed him in a cab to the hospital, taking no special care to prevent movement of his head.

On admission, the patient was quite conscious, and had been so ever since the accident, which he described with some minuteness. He had not been sick, pupils were natural, there was no deafness, no hæmorrhage from the ears, no facial paralysis, no strabismus, no loss of sensation over head and neck; he spoke fluently and distinctly, there was no loss of memory, there was no bruise, swelling, or tenderness over the part said to be struck, but the patient is an expert diver, and persisted in his statement. Sensation was much impaired in the hands and feet, which were cold, bluish, and numb; he complained also of burning and tingling pain in the upper extremities, extending from the fingers to the shoulders; sensation was apparently not impaired in any other part. Respiration was nearly entirely diaphragmatic, the intercostal muscles apparently hardly assisting at all; there was some slight facial cyanosis. He had lost all control over both arms and the right leg; when these limbs were raised they fell helplessly again; over the left leg he had more control, but the power of movement was much impaired. He had not micturated since the accident; there was priapism on passing a soft elastic catheter, and on touching the skin near the penis; patellar-tendon reflex was not impaired; there was no ankle clonus. There was occasional aching pain at the back of the root of the neck in the median line, not very circumscribed; this was increased by movement of the head from side to side, and from before backwards, and on pressing the head downwards on the spinal column; there was also great tenderness in the same region, but no swelling, bruise, or apparent displacement; but a very complete examination was not made.

The patient was placed on his back upon a hard mattress with a pad under the back of the neck, and the head and neck were kept immovable by means of heavy sandbags. He was ordered milk diet and beef-tea.

June 2nd.—Had a sleepless night; urine natural, drawn off by a soft elastic catheter.

3rd.—Slept fairly well after a subcutaneous injection of morphia; urine drawn off, natural.

4th.—Feels a little better; slept after a morphia injection; can pass his urine now; no priapism; urine natural.

5th.—Sleepless night without morphia; can cough, but with difficulty.

6th.—Better; good night after a morphia injection; increased power over limbs; pulse 56.

7th.—Restless night without morphia; has not defecated since the accident (seven days); tongue slightly coated with white fur; pulse 70.

8th.—Bowels open freely; good night after morphia draught.

11th.—Restless night without morphia; aching pains in lumbar back and between scapulæ, more acute at night; temperature 99·6°; tongue coated with white fur; pulse 56. Left leg normal; can raise right thigh and keep it flexed for a short time; if the left forearm be flexed he can keep it in that position for a short time, and move the left arm from the side. There is no improvement in the right arm.

14th.—Respiration now slightly thoracic; less pain in the back; slept fairly well after morphia draught; appetite improving; bowels not open for three days; temperature 99°; tongue clean; power over limbs less impaired; left leg natural; right leg natural excepting the toes, which cannot be flexed and are cold and numb; left arm much better, can flex elbow and abduct shoulder-joint, and when the limb is raised it can be kept in that position for a short time, the shoulder-joint can also be slightly flexed; right arm, flexion of elbow improved and slight power of flexion and abduction of shoulder-joint; hands are powerless; the tingling, burning, and numbness of upper extremities are better and confined to the hands; they have been kept wrapped in cotton-wool, the tingling disappears if the hands are well rubbed, but it is increased by cold and washing; the neck can be slightly flexed by the patient, and there is freer rotatory and lateral movement, but all movements are still attended by pain.

July 14th.—Has steadily improved in every way; though weak is rapidly gaining strength; has been up for some time and goes out of doors daily; paralysis is limited to right arm and hand; there is no tingling; the neck is supported by a firm leather collar which keeps it immovable; there is still slight pain in the region of the fracture. Patient is on full meat diet.

Aug. 8th.—There is now only some stiffness in the movement of the right hand, which cannot be so quickly and firmly closed as the left, but the grasp is fairly strong. There is stiffness on turning the head and slight pain in the neck, as before. He is much stronger, and attends as an out-patient. The collar is still worn.

The temperature has never been above 99°, except on two occasions soon after admission, when it rose at night to 100·8°.

Remarks.—This case is especially interesting as an example of spinal concussion resulting from a blow on the head. As M. Duret has pointed out in these cases, there were symptoms especially referable to lesions of the medulla oblongata, which suffers from the resistance it offers to the sudden passage of the cerebro-spinal fluid from the cranial cavity to the neural canal. In addition to the concussion of the cord from the increased tension of the cerebro-spinal fluid, there was probably some additional injury to the cervical portion of the cord, with a special train of symptoms. This might be accounted for by supposing that there was a fracture of some part of the cervical spinal column, and the physical signs present on admission would to a certain extent support such an hypothesis. The absence of any evidence of a blow on the vertex, although uncommon, as well as the slight character and short duration of those symptoms especially referable to the general concussion of the cord, may be justly ascribed to the buoyancy of the water, which lessened the severity of the blow; those symptoms which depended on the severer lesion caused by the fracture, although temporary, were of much longer duration.

QUEEN'S HOSPITAL, BIRMINGHAM.

CASE OF PRIMARY ENCEPHALOID GROWTH OF LUNG; NECROPSY; REMARKS.

(Under the care of Dr. SUCHLING.)

FOR the following notes we are indebted to Mr. Sidney C. Lawrence, M.R.C.S., L.R.C.P. Lond., house-physician.

T. C——, a man, aged sixty-one, was admitted on Aug. 5th, 1884. There was no history of phthisis or cancer

Digitized by Google

in the family. The patient had never had any previous illness except rheumatic fever twenty years ago. When in good health he weighed 14 st. About twelve months ago his friends noticed that he was getting thin, and at that time he found the slightest exertion tired him. He had no pain, but suffered from shortness of breath and cough, with profuse expectoration of whitish phlegm. He attended the hospital on June 16th as an out-patient, and on examination dulness was found over the lower lobe of the right lung, with amphoric râles and pectoriloquy. A mitral systolic bruit was also heard. There was slight œdema of the legs. He was treated as an out-patient for a month, but not improving, was admitted into the hospital, having had several attacks of hæmoptysis shortly before.

On admission he was greatly emaciated, the expectoration was profuse, viscid, could scarcely be poured out of the cup, and resembled red-currant jelly. Under the microscope leucocytes, epithelioid cells, and red blood-corpuscles were seen in abundance. There was no visible enlargement of the right side of the chest, but it was found that the circumference of the right side was eighteen inches and a half opposite the nipple, while that of the left side was seventeen inches. Vocal fremitus was absent over the lower lobe of the right lung. Elsewhere it was well-marked. The cardiac impulse was in the fifth space, just internal to the nipple-line, and there was a mitral systolic bruit. The respiratory movements on the right side were greatly diminished. The percussion note above, over, and below the right clavicle was impaired, absolute dulness being reached at the fifth space in the nipple-line and at the fourth space in the mid-axillary line. In the right supra-spinous fossa and inter-scapular region the percussion note was much impaired, absolute dulness being reached at the eight rib and extending to just below the costal arch. Friction was heard under the right clavicle, and at the right base amphoric breathing with amphoric râles. Friction was also heard at two or three points in the inter-scapular and supra-spinous regions. At the left apex expiration was prolonged, and there was a little crepitation. The liver was pushed down to the level of the umbilicus; it was evidently not enlarged, for the anterior border was thin and could easily be grasped; it descended very little on a deep inspiration. The spleen was not enlarged. No enlarged glands or engorged veins could be seen, nor were the intercostal spaces obliterated.

A hypodermic needle was passed into the pleural cavity just below the inferior angle of the right scapula, and a syringeful of serous, flaky fluid, with a sanguineous tinge, was with difficulty obtained.

On Aug. 28th a needle was again introduced, but no more fluid could be withdrawn. At this time absolute dulness extended to the fourth rib in the nipple-line, but had not extended upwards in the axillary or infra-scapular regions. The breath sounds were more distinct. The hæmoptysis continued, but in diminished quantity—about two ounces daily.

Sept. 4th—The patient was in much the same condition, but the liver was not so much depressed. Vocal resonance over the back of the lower part of the right lung was well marked, but the vocal fremitus was very slight. His weight at this date was 9 st. 1 lb. The line of absolute dulness in the nipple-line reached the third space, in the axilla the fifth space, and at the back to the sixth space. Friction and crepitant râles over the dull urea still persisted.

11th.—Patient weaker, though quite free from pain. Sputum more copious and blood-stained. Pulse 98; respiration 30.

14th.—Bronchial breathing, amphoric râles and pectoriloquy were well marked, and it was evident that there was a cavity at the right base. The vocal fremitus at this time was well marked.

20th.—Patient had gradually been losing strength, and was now very feeble. Pulse 102, small and irregular. He stated that he had no pain at all, but only feels exhausted. Had had diarrhœa for a few days, which was checked by bismuth.

The patient died on Sept. 21st from pure exhaustion.

The temperature during the first month that the patient was in hospital was of a continued type, averaging 100°; but during the last three weeks of his life it was generally normal, with an occasional elevation. The urine contained a trace of albumen, but was otherwise normal.

Necropsy (Sept. 22d).—Body much emaciated; rigor mortis slightly marked. The right lung was covered with rather a thick layer of recent lymph; no effusion in the pleural cavity. The pleura was much thickened, the base of the lung being firmly attached to the diaphragm. The right lung weighed 90 oz.; the outline was well preserved, but it was nearly solid. On section three cavities were found, one at the apex as large as a walnut, and two at the base, each as large as a small orange. Miliary tubercles were scattered throughout the lung. The lower lobe of the lung was occupied by a very large patch of yellowish firm material; surrounding this mass were a number of secondary foci of similar tissue. The patch had softened in two places. The left lung weighed 42 oz., was adherent to the chest wall, and was œdematous; it was studded with small patches of a white colour, as in a catarrhal pneumonia, but of a firmer consistence, each containing a bronchus in its centre. The heart weighed 10½ oz.; all its cavities contained coagula; the segments of the mitral valve were thickened and the orifice dilated; the left ventricle was a little hypertrophied. The aorta was atheromatous. The liver weighed 70 oz., was much congested, and "nutmeggy" in appearance. The mesentery was studded abundantly with miliary tubercle, but there was no peritonitis. There were well-marked tubercular deposits at numerous points in the small intestine. The spleen was normal. The kidneys were both congested and with diminished cortex, but were not typically granular. Microscopically, a section of the growth in the right lung was made, and therein were to be seen large and irregular epithelioid cells with well-marked nuclei crowded in definite alveoli, within whose walls were smaller cells. Some of the large cells were granular, and apparently undergoing fatty degeneration. An examination of the sputum revealed the presence of the tubercle bacillus in considerable numbers.

Remarks by Dr. SUCKLING.—Primary encephaloid disease of the lung is exceedingly rare. The case at first was supposed to be one of phthisis; but when in hospital the enlargement of the right side, together with the displacement of the liver, suggested some new formation. The sputum was like red-currant jelly, and this is said to characterise malignant disease of the lung. The physical signs—viz., absolute dulness with abolition of vocal fremitus, and displacement of the liver—were those of pleuritic effusion, but there was very little fluid. This was also characteristic of malignant disease of the lung, the new growth filling up the air cells and bronchi, and so obliterating the vocal fremitus. The softening, which took place rapidly, altered the physical signs. The complete absence of pain in this case is remarkable and unusual. The enormous enlargement of the lung could only be due to a new growth. Cancerous disease and phthisis are usually supposed to be antagonistic, and certainly are rarely combined. In this case the tuberculosis seems to have been set up by the inflammatory softening in the right lung. The increased weight of the left lung was chiefly due to its congested condition.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Distribution of Tubercle Bacilli in the Lesions of Phthisis.

AN ordinary meeting of this Society was held on Tuesday last, Dr. Priestley, Vice-President, in the chair. The following gentlemen were elected Fellows:—Mr. J. F. Bullar, Mr. Lovell Drage, Dr. W. A. Duncan, Mr. F. Swinford Edwards, Mr. Kendal Franks, Mr. C. C. Fuller, Mr. H. T. Griffiths, Mr. C. E. Jennings, Dr. J. Johnston, Dr. J. S. Keser, Dr. A. Oakes, Mr. G. R. T. Phillips, Dr. E. Stewart, Mr. J. Raglan Thomas, and Mr. Bilton Pollard.

The discussion on Dr. Kidd's paper was adjourned to the next meeting, January 13th, 1885.

Dr. PERCY KIDD read a paper on the Distribution of the Tubercle Bacilli in the Lesions of Phthisis. The present paper was based upon an examination of eighty cases, and included two cases of malignant disease of the lung, two cases of sacculated bronchiectasis, and one case of dysenteric ulceration of the intestine. With these exceptions all the cases may be described as "tuberculous." In more than half the cases the lung was examined, in twelve cases the larynx or trachea, in thirteen the intestine, and in thirteen the lymphatic glands. Various other parts were examined in a few instances. With regard to the lung, the object

Digitized by Google

kept in view was to examine the various lesions comprised in the phthisical process, and to ascertain their connexions with the development of the tubercle bacilli. These bacilli are invariably found in pulmonary cavities, and in nearly all cases in softening caseous material, provided that the morbid process be associated with a tuberculous affection. On the other hand, the fetid contents of a cavity in two cases of saccular bronchiectasis contained numerous micrococci, but no tubercle bacilli. In most instances these bacilli were detected in the nodular lesions of phthisis, though their number was almost always small, whereas in the three cases of acute miliary tuberculosis examined they were in many nodules very abundant. It is probable that in all cases, whether of acute miliary tuberculosis or phthisis, some stage of the growth of the nodules is associated with the presence of these micro-organisms. The distribution of the bacilli in the so-called caseous pneumonia appears to be very irregular. Generally speaking, where the caseation is uniform and firm no bacilli can be found. But where the caseous process is commencing, or where softening is going on and microscopical cavities are present, bacilli are often seen in great numbers. Where the caseation is recent bacilli are usually scattered among the caseating epithelioid cells, whereas in the later stages they are more often collected in groups, and their distribution is very circumscribed. In this, as well as in the nodular form, the bacilli are usually situated in the caseating alveoli, more rarely in the alveolar walls. Both in the nodular and caseous pneumonic forms bacilli are often found in the infiltrated walls of the small bronchi. Where fibroid induration was pronounced no bacilli were found. Their presence or absence in caseous material seems to depend mainly on its age. The older the caseation the less is the chance that bacilli are present, unless softening occur, when their appearance is certain to take place sooner or later. It is probable, as Koch suggests, that the spores of the bacilli may lie dormant for a very long time, and when suitable conditions are provided may develop into mature bacilli. In the larynx, intestine, and lymphatic glands the presence of the bacilli seems to depend on similar conditions. The fact that the same micro-organisms are found in tuberculous disease of such remote parts as the pia mater, peritoneum, lung, intestinal and genito-urinary tracts, shows that their association with tuberculosis can be no mere accident.

Dr. CREIGHTON thought that the investigations of Dr. Kidd and others ought to remove all doubt of the statement that rod-shaped organisms are universally found in tubercular lesions. Dr. Kidd confirmed most of Koch's original statements. The bacilli were wanting in dry caseous matter, and were much more numerous at the growing periphery of tubercular material. The bacilli were most abundant where the degenerative process is going on in the way of softening of the consolidation. In all forms of granulomata it may be said rod-shaped organisms are to be found. Recently Lustgarten, working at Leipsig (*vide* THE LANCET, *ante* p. 1017), had found the rods in syphilitic gummata. These facts pointed to a general law that all nodular new growths which had great tendency to generalisation formed a favourable nidus for the development or presence of rod-shaped organisms. In some of Dr. Kidd's specimens spherical organisms were to be seen in small cavities. Klebs and Toussaint had found that in cultivating media the spherical organism abounded if inoculation be made with bacilli. Rod-shaped organisms, if cultivated in fluid media, grew into micrococci. The separation of one micro-organism from another was the object of Koch's demonstration at the International Medical Congress of 1881. Koch, however, made no use of the dry method of cultivation in his latest researches. Koch adopted commonplace devices to prevent the presence of the bacteria of putrefaction. If the gelatine became fluid the test-tube was thrown away on the ground that the tube had become contaminated with tubercle bacilli. Mr. Cheyne made no attempt to test the validity of Koch's method, for he used the same material from Berlin as Koch used. Koch, therefore, relied on successive inoculations to obtain a pure breed of tubercle bacilli, and in this method fallacies might lurk.

Dr. C. T. WILLIAMS thought that the previous speaker had wandered from the subject. Koch seemed to prove his point carefully so far as Dr. Williams knew. Where bacilli are most abundant is amongst the giant cells, according to Koch, but this doctrine Dr. Kidd was unable to substantiate. The ring of bacilli at the periphery of a giant cell seemed to show that nature endeavoured to defend herself against the invading bacilli. The mode of spread by inhalation required further investigation. The spread of bacilli by blood-vessels and lymphatics would probably account for some of the ascertained facts. Spread by direct continuity was another method of dissemination. Ribbert had made observations on the fowl (THE LANCET, vol. ii., 1883, p. 190). Four zones were described in the tubercular lesions; the bacilliferous zone was the third, reckoning from the centre, and also many bacilli were seen in the outermost or vascular zone, and here they projected into the veins. If tuberculous material be injected into the trachea, then the lungs and mesenteric glands only were affected; whilst if the virus were inoculated subcutaneously a generalised tuberculosis resulted.

Mr. BLAND SUTTON said that in the liver of fowls he had detected enormous numbers of giant cells which abounded in bacilli. The daphnia or water-flea inhabited fresh water ponds, and possessed an external shell similar to that of an ordinary lobster. The bacilli penetrated by the alimentary canal, and were immediately beset by white blood-corpuscles, which corpuscles, coming together, became fused and formed a giant cell. A struggle for existence then took place between the bacilli and the giant cells, with different results in different cases.

Sir ANDREW CLARK congratulated Dr. Kidd on his interesting and important paper, which formed a substantial addition to our knowledge on the subject. He could not concur in the statement that the bacillus was sufficient to explain all the lesions of phthisis. He defined phthisis as the assemblage and progression of states associated with or dependent upon ulcerative or suppurative destruction of more or less circumscribed non-malignant deposits or consolidations of the lungs. And under this definition chronic interstitial pneumonia or fibroid phthisis would also fall, for there occurred ulcerative or suppurative destruction of tissue, together with the symptoms, which could not be distinguished from those of ordinary phthisis, and yet in the lesions no bacilli were to be found. In eleven cases of ulcerative interstitial pneumonia or fibroid phthisis no tubercular bacilli have been found though carefully investigated by himself and his house-physicians. A case of dry pleurisy, which lasted for a period of eighteen months, in a gentleman, was narrated. Eighteen years after the pleurisy osteo-arthritis set in, and the signs of a contractile disease in the left lung were made out. There were signs of dry cavities in the lungs, and asphyxia terminated death from hæmoptysis. Here there was no evidence of tubercular bacilli in microscopic sections of the diseased tissues. It must be remembered, also, that no bacilli were found in some cases of acute miliary tuberculosis; and further, that in some cases no bacilli were to be detected until softening had taken place, so that these facts led him to doubt the causal connexion of the bacilli with phthisis. Again, cases of caseous pneumonia had a life history which was totally different from the life history of what we call tuberculosis. The true criterion of disease was to be found in the whole and complete life history of a malady, and not in the anatomical lesions which were induced by something lying behind and working beneath them.

MEDICAL SOCIETY OF LONDON.

Intussusception.

AN ordinary meeting of this Society was held on Monday last, Mr. Arthur E. Durham, President, in the chair.

Mr. F. TREVES read a paper on Intussusception. Thirty per cent. of all forms of obstruction (except hernia and congenital malformations) were cases of intussusception. Of the anatomical forms of intussusception, 30 per cent. were enteric, 18 per cent. were colic, 44 ileo-cæcal, and 8 were ileo-colic. The enteric forms were most common at the lower part of the jejunum and were small; the colic forms were mostly to the left of the transverse colon. A description was given of the ileo-colic and ileo-cæcal forms. The colic forms were as a rule chronic. The other forms were acute or subacute. The ileo-colic was as a rule acute in its course. Of the clinical forms, four kinds were described. The ultra acute was very rare, and terminated fatally in twenty-four hours; the acute, lasting from two to seven days, numbered about 48 per cent. of all cases of intussusception; the subacute, lasting from seven to thirty days, were about 24 per cent.; and the chronic, lasting over thirty days, occurred

Digitized by Google

about 18 times out of every 100 cases. The disease occurred mostly in children, as the table of ages showed :—

Proportion at Various Ages.

Before	11 years	... ...	53 per cent.
Between	11 and 20 years	... ...	12 ,,
,,	21 and 40 ,,	... ...	20 ,,
,,	41 and 60 ,,	... ...	11 ,,
Beyond	60 ,,	... ...	4 ,,

Fifty per cent. of all cases occurred under ten years of age. Acute forms were most frequent in the young, and chronic kinds between the ages of twenty and forty. The pathological changes were chiefly of two kinds : first, obstruction of the bowels ; and secondly, strangulation of the intussusceptum. The two changes need not coexist ; mere invagination does not of necessity involve either, as, for example, in the early stage of chronic intussusception. In strangulation of the intussusceptum there was compression of the mesenteric or meso-colic vessels and constriction at the neck of the intussusceptum. Obstruction of intestines might be due to four factors :—(1) The orifice of the intussusceptum becoming converted into a slit, and getting opposed to the intussuscipiens : (2) the inner and middle cylinders becoming bent ; (3) these cylinders may become enormously thickened ; and (4) the lumen may become plugged by blood, &c. The intussusception may be irreducible owing to adhesions about the neck or over the whole surface ; these adhesions cannot be diagnosed ; they may be absent in cases of six weeks' duration, and present in others of three days' duration ; they are met with in 80 per cent. of chronic cases, and 40 per cent. of acute ones. Swelling of the intussusceptum, bending or twisting of the middle cylinders, and the valvular constriction in some cases of the ileo-colic form were other causes of irreducibility. Spontaneous cure by elimination cannot occur in certain cases of the chronic form, and certainly not in the ultra acute form, but it may occur in the gravest case when the patient is *in extremis*. Spontaneous elimination takes place in about 40 per cent. of all cases, but this is no guide to the mortality, for the whole of the forty do not live. Spontaneous elimination occurs in the ileo-cæcal form in 20 per cent., in the colic form in 28 per cent., and in the enteric form in 61 per cent., so that it is most rare in the most common form. It occurs in 2 per cent. under two years of age, in 6 per cent. between two and five years, in 38 per cent. between six and ten, in 40 per cent. between eleven and forty, in 44 per cent. between forty-one and sixty, and in 46 per cent. beyond sixty years of age, so that it is most rare in patients among whom intussusception is most common. Spontaneous elimination has occurred at the end of the third or fourth day, and as late as the sixth or seventh month. The great bulk fall between the tenth and thirtieth day. In over 40 per cent. of the subjects of elimination death follows from effects arising out of the original lesion or the elimination. The general mortality of intussusception is 70 per cent. Between the ages of eleven and twenty it is 28 per cent., between twenty-one and forty 32 per cent., between forty-one and fifty 36 per cent., between fifty-one and sixty 50 per cent., and beyond sixty 85 per cent. The mortality is highest when spontaneous elimination is most common. In a hundred cases of intussusception in children under eleven it may be reckoned that not more than twelve will undergo cure by elimination. Spontaneous reduction or the formation of a fistula above the invagination (one case) are other modes of spontaneous cure. The treatment was discussed for acute and subacute cases only. Opium first, as it gives rest to the intestines, relieves pain, and diminishes shock. Nothnagel produced all the various forms of intussusception in animals by means of electrodes. Opium gives better effect to the subsequent treatment. Feeding is of no moment in acute cases; thirst may be relieved by enemata. Enemata with a view to reduction should be adopted as soon as the patient is under the influence of opium. In really acute cases they do no good after the second day. Chloroform should be administered in children. The best positions were the knee and head or knee and elbow ; sometimes the lateral abdominal. Inversion was no good. A tumour could be felt either through the parietes or per rectum in nearly 50 per cent. of the cases, and the effect of enemata on the tumour should be watched. Massage, electricity, carbonic acid, enemata, and metallic mercury were useless and wasted time. Laparotomy should be resorted to without delay, and should be a first, not a last, resort. The mortality of the operation was high, but would probably be much less if performed earlier, and when the patients were less exhausted. In really acute cases operation should be performed within forty-eight hours, and in infants, if possible, within twenty-four hours. The *modus operandi* was next discussed, the median incision being recommended in all cases. The general mortality was 72 per cent. in thirty-three recorded cases ; when reduction was easy it was 30 per cent., and when difficult it was 91 per cent. Resection should be done if the intussusception be irreducible or gangrene have set in.

Dr. HABERSHON spoke of the difficulties of diagnosis and of the best plan of treatment. The treatment naturally followed the clinical course—acute, subacute, and chronic. Medical treatment was only available in the acute cases. Belladonna and the injection of free diluents have been followed by success. When failure is experienced in the employment of medical agencies, then operation should be done. He asked Mr. Treves to give the precise time at which operations had been performed. The introduction of a bougie in the rectum had been of value in starting reduction. Intussusception was a gradual process, and hence the importance of securing early treatment.

Dr. W. H. DAY narrated a case of intussusception in which the use of belladonna combined with four copious warm water enemata resulted in success.

Mr. BERNARD PITTS gave an outline of a case of a child aged five who suffered from acute intussusception. The intussusception could be felt in the rectum ; in this case manipulation followed by inflation of the bowel was combined with inversion of the patient, and attended with success.

Mr. BOYCE BARROW remarked that the application of ice over the intussusception was of much importance.

Mr. PICKERING PICK considered that intussusception and strangulated hernia were not identical. It had always been difficult for him to advise early abdominal section when he remembered that there were rational chances of recovery without operation. Allusion was made to the difficulty and occasional impossibility of returning the bowel in the abdominal cavity. He would rather resect the intussusception than perform abdominal section and make an artificial anus.

Dr. C. H. ROUTH advocated the use of belladonna in obstruction of the intestines, and especially in cases of intussusception in children.

Mr. ROYES BELL related two cases which had been under his care. The first case was a fatal one ; reduction was impossible, even after abdominal section. The second case recovered after ineffectual attempts at reduction by means of inflation.

Mr. W. ROSE confessed that he had never understood statistics better than those brought forward by Mr. Treves. Early operation in young children was most necessary. The operation was, no doubt, one of great difficulty. He preferred excision of an irreducible intussusception to the formation of an artificial anus.

Mr. PEARCE GOULD asked by what data the clinical nature of the case could be recognised. How long is opium to be given before resorting to other means? We should be careful to apply remedies thoroughly on a first occasion, and if failure resulted other measures should be tried. Enemata set up violent peristalsis, and ought not to be resorted to as a means of feeding the patient. He preferred opium to belladonna.

Dr. RADCLIFFE CROCKER was convinced that for belladonna to be of use much larger doses must be employed than those recommended by Dr. Day and Dr. Routh.

Mr. TREVES, in reply, preferred opium to belladonna, as there was not time to use many drugs. Mere vague rubbing of the abdomen was practically useless. M. Grisset had extensively tried ice in every way, but the action of ice was, in animals at least, to increase the peristaltis. As to the chance of recovery *versus* laparotomy, it must be remembered that the fatality of laparotomy would probably be much less if the operation were performed early. The severity of the symptoms might indicate the acuteness or subacuteness of the clinical course. Enemata were perfectly useless after the second day.

EPIDEMIOLOGICAL SOCIETY.

AT a meeting of this Society, held at Chandos-street, Cavendish-square, on Wednesday, Nov. 12th, Dr. NORMAN CHEVERS, the President, delivered the inaugural address. He commenced by saying that since the Society last assembled, death had taken from the Association one who,

Digitized by Google

although younger than most of them, was second to none as a man of science. The daily business of the life of John Netten Radcliffe was epidemiology, and when that life closed so prematurely there was not in Christendom any investigator of disease to whom the title of "epidemiologist" was more justly due than it was to him, an inquirer as honest as he was able, upon whose brief and by no means painless, mundane existence the divine light of truth was bountifully shed. Dr. Chevers then brought before the Society, in the form of questions, several observations on the subjects of endemic quinsy, inflammation of the external meatus of the ear, diphtheria with mumps, and boils in India. Having also related remarkable cases of jaundice and colic, he made some observations on herpetic fever and concluded with some remarks on dysentery. In the address delivered at the opening meeting in 1883 he had made some allusion to the occurrence of dysentery in London, showing that the last prevalence of dysentery occurred between the years 1840 and 1847. The details were recorded by Dr. Baly, and Dr. Chevers in his own person had convincing evidence that the malady was true dysentery. The almost complete subsequent immunity of London from this disease is proved by the fact that two distinguished hospital physicians of middle age lately said they had never seen a case of dysentery originating in London. Nevertheless, the Registrar-General's returns, as cited in the public press, state that "119 [deaths occurred during the week ending 18th August, 1883, in London] from *diarrhœa and dysentery*." In one week in the previous month of July the newspaper gives 351 deaths from dysentery. Making due allowance for inaccurate citation by non-professional reporters, this assertion of the occurrence of a multitude of deaths from dysentery in a city whose physicians have never seen English dysentery will naturally appear somewhat perplexing. Dr. Chevers said that the Registrar-General was as wrong in massing together cases of these perfectly distinct maladies, dysentery and diarrhœa, as an ornithologist would be if he classed the owl with the sparrow. He had lately spoken on this matter to a very high non-professional authority, who considered that the anomaly probably arose from a prevalence of cases of "dysenteric diarrhœa," a disease of which Dr. Chevers then heard for the first time, and in the existence of which, either at the present or any other time, he confidently disbelieved, diarrhœa and dysentery being two perfectly distinct entities always to be differentiated by observing the symptoms and washing the stools. The erroneous belief in the existence of "dysenteric diarrhœa" probably arose from the fact that grave dysentery is not always attended with severe pain. A careful search for indigenous dysentery in London and its suburbs would probably lead to the discovery of genuine cases.—In the discussion which followed Sir Joseph Fayrer, Sir W. Guyer Hunter, Surgeon-General Gordon, Surgeon-General Murray, Inspector-General Lawson, and Drs. Pringle and Saunders took part.

MEDICAL OFFICERS OF HEALTH SOCIETY.

AT a meeting of this Society held on Friday, Nov. 1st, at 1, Adam-street, Adelphi, Dr. T. O. Dudfield, President, in the chair,

Mr. ALFRED SPENCER, of the Metropolitan Board of Works, read a paper on the Supervision of Noxious Trades. Mr. Spencer referred to the effect of the Metropolitan Building Act of 1844, Sect. 65 of which prohibited the erection of any dwelling within fifty feet of a building used for the businesses of a blood-boiler, bone-boiler, fellmonger, soap-boiler, tallow-melter, tripe-boiler, slaughterer of cattle, sheep, or horses, and any other like business, offensive or noxious. It was also forbidden to carry on any such business within forty feet of any public way and fifty feet of a dwelling; and any existing business of this character within these distances was to be abandoned at the end of thirty years. By themselves these clauses would have led to the abolition of such places within thirty years, but a later section gives the justices power to mitigate the penalty, provided the best means were adopted for preventing nuisance. In 1874 an Act was passed which repealed the last section, and thus certain businesses came to be prohibited, while others could only be established by consent of the local authority. The Metropolitan Board of Works, under this Act, made regulations for slaughter-houses, which have been very beneficial in their operation, and as many as 620 out of 1429 have been abolished. Offensive businesses are mostly situated in Bermondsey, in Belle Isle, Islington, and Southwark. A second set of bye-laws under this Act deals with the businesses of a blood-boiler, bone-boiler, a manure manufacturer, soap-boiler, and tallow-melter. The means for preventing nuisance in these businesses was stated in detail. Mr. Spencer then dwelt on the qualifications necessary in the inspector for influencing the masters and men engaged in them. A short account was then given of trades dealt with by the Alkali Works Regulation Act of 1881, which takes cognisance of works for sulphuric acid, for gas liquor, for nitric acid, and sulphate of ammonia. Other businesses were then briefly considered, such as brick and ballast burning, cement making, &c., and in conclusion Mr. Spencer claimed that the London of to-day is far more free from nuisance resulting from trades in consequence of the restrictions under which they are placed than formerly.—In the discussion which followed, the President, Drs. Saunders, Gwynn, Iliff, Kelly, and Corfield, Mr. Rogers, and Mr. Shirley Murphy took part.

Reviews and Notices of Books.

A Practical Treatise on the Medical and Surgical Uses of Electricity. By GEO. M. BEARD, M.D., and A. D. ROCKWELL, M.D. Fourth Edition. London: H. K. Lewis. 1884.—This treatise, as our readers probably are aware, emanates from America, and for this last edition Dr. Rockwell is solely responsible. It is very large, and deals at length, if not exhaustively, with every phase of electro-therapeutics. In fact, the author manages to fill nearly 800 octavo pages. The book, it may be urged, is not so big as the last edition of Duchenne's classic treatise on "L'Electrisation Localisée," but then the large bulk of the latter was due mainly to the additions made by its author to scientific medicine. Duchenne used electricity as a means of treatment it is true, but still more largely he used it as a means of investigation, and if Duchenne's work grew in bulk, its bulk was never disproportioned to its scientific value. Dr. Rockwell is a great believer in the therapeutic value of electricity, and the size of the book is proportioned to the extent of his belief. It is not unlikely that English readers may come to the conclusion that many of Dr. Rockwell's patients might have recovered even without his aid, or by means of therapeutic measures other than electricity. It may be laid down as a rule of medical ethics that while we do well to be sceptical in accepting new statements as to the value of all new modes of treatment, we are especially bound to use our scepticism in those methods of treatment which necessitate on the one hand the repeated visits of the physician to his patient, and on the other hand the constant "refreshing" (to use a legal phrase) of the physician by his patient. A glance through this work will show that Dr. Rockwell recommends the use of electricity for many conditions for which it is not applied to any great extent in this country. It is true that electricity may be used in a great many conditions in which a local stimulation of the tissues is indicated, but we cannot but feel that in the best interests of the profession as well as patients something should be left for time to accomplish, and to be brought about by what Lord Beaconsfield called "the magic of patience." We can only hope that the general reader will not be carried away by Dr. Rockwell's statements, and that he will carefully study and verify them before he begins to make an almost invariable use of electrical currents for all the protean forms of disease. To such as have a knowledge of neuro-pathology, Dr. Rockwell's work may prove of value for occasional reference, but, notwithstanding its size, it does not seem to us to be particularly well filled with references to the latest and most trustworthy authors on the subjects of which it treats. For example, Durham and Forster's cases of hydatid tumour successfully treated by galvano-

Digitized by Google

puncture are given at p. 698, but no mention is made of Dr. Fagge's subsequent experience of similar benefit derived from simple puncture. There are many practical hints and details scattered throughout the book, which will certainly prove of service to those who are wishing to use electricity for the benefit of their patients. This is the strong point of the book, and we do not hesitate to say that while the sanguine reader is likely to be often disappointed when he comes to put Dr. Rockwell's treatment into practice, the reader with judgment and knowledge will get many valuable practical hints from a perusal of the work.

A Manual of Diseases of the Throat and Nose. By MORELL MACKENZIE, M.D. Vol. II.: Diseases of the Œsophagus, Nose, and Naso-pharynx. London: J. and A. Churchill. 1884.—Some of the special features of this work are its wealth of accurate reference to related literature; its carefully planned histories of the various diseases; the conciseness and clearness of its language, and the thoroughness of its pathology so far as that is possible. It is needless to say that the volume, whilst bearing the impress of Dr. Mackenzie's authorship, could hardly have been the labour of one mind when we remember the time which is likely to have been at the disposal of the author for the past twelve years during which the work has been in progress. Indeed, Dr. Mackenzie expresses his thanks to several friends and assistants who have aided him in clinical investigations and literary researches, and in particular he acknowledges his deep obligations to Mr. C. L. Taylor for his invaluable help during the past four years. The poverty of real information concerning acute œsophagitis, more especially in infants, is obvious from a perusal of this section of the volume. We are convinced that the greatest nonsense is talked in connexion with inflammatory affections of the œsophagus amongst infants. Listening to one class of physicians, whose experience we cannot but think is not the result of observation of cases either during life or after death, we hear that the œsophagus is a desert in respect of disease. Now, in our view there can be no doubt that certain degrees of inflammatory action are by no means uncommon both in infants and others; and the cause of such irritative disturbance will probably be found to be the illegitimate use of spirits and many other irritant articles of ingestion. It is a fact requiring further explanation than we can find for it that the more specific diseases of the neighbouring organs do not greatly tend to propagate themselves along the œsophagus. Dr. Mackenzie has seen but two fatal cases of diphtheria of the gullet, one in a child aged three, and the other in a boy aged six. In the chapter on Rupture of the Gullet Dr. Mackenzie relates some experiments which seem to prove that the lower third of the œsophagus is the region of least resistance; that rupture from direct pressure applied within the gullet always takes place in a longitudinal direction and that the mucous membrane offers greater resistance to strain than the muscular covering. The work has been well indexed by Mr. Mark Hovell.

Diseases of the Spinal Cord. By BYROM BRAMWELL, M.D., with 183 Illustrations. Second Edition. Edinburgh: Young J. Pentland. 1884.—We have already fully reviewed this excellent book (THE LANCET, 1882, vol. ii., p. 745). The author is to be congratulated on the appearance of a second edition. The original plan of the work has been for the most part adhered to, though every page has been subjected to careful revision. The sections devoted to the pathology of individual lesions have been placed under the special diseases, the functional affections have been more fully considered, and a considerable space has been given to the important and difficult subject of concussion of the spine, and the method of examining "railway cases." Many of the old illustrations have been redrawn, and a large number of new figures, both woodcuts and chromolithographs, have been added. The excellence of the chromolithographs calls for the highest commendation. The second is a still better guide than the first edition, good as that was.

Fat and Blood. By S. WEIR MITCHELL, M.D. Third Edition, revised, with additions. Philadelphia: J. B. Lippincott and Co. London: Southampton-street, Strand. 1884.—This little book of 162 pages ought to be carefully studied by every practitioner of medicine. Although the treatment, which is here considered in all its aspects, has special reference to the methods of renewing the vitality of feeble people, yet we are convinced that many hints which have a wider application may be gathered from the pages of the work. We shall content ourselves with a single quotation, from which will be gathered much that we could hardly express in better terms:—"As regards the acceptance of this method of treatment I have to-day no complaint to make. It runs, indeed, the risk of being employed in cases which do not need it and by persons who are not competent, and of being thus in a measure brought into disrepute. As concerns one of its essentials—massage—this is especially to be feared. It is a remedy with capacity to hurt as well as to help, and should never be used without the advice of a physician, nor persistently kept up without medical observation of its temporary and more permanent effects."

Elements of Modern Chemistry. By ADOLPHE WURTZ, Senator, Member of the Institute, &c. Second American Edition. Translated and edited, with the approbation of the Author, from the Fifth French Edition, by W. H. GREENE, M.D., Professor of Chemistry in the Central High School, Philadelphia, &c. London and Philadelphia: Lippincott. 1884.—It is not wonderful that Professor Wurtz's little book has run quickly through edition after edition, for it is clear and simple, and the author's name is illustrious. Dr. Greene is an excellent translator, and the American edition is printed on good paper and in good style. This very considerable allowance of praise is all we can afford. We find no element of novelty in the book, and can see no reason why it should be selected as an elementary text-book in preference to a good many others which might be mentioned. It is indeed so like the ordinary run of books of the class that we should find little to say of it even if it were a first instead of, virtually, a fifth edition.

The Journal of Anatomy and Physiology. Conducted by Professors G. M. HUMPHRY, W. TURNER, and J. R. M'KENDRICK. Vol. XVIII., Part IV.—This part contains the following memoirs:—Cleland: Terminal Forms of Life. Sutton: Rickets in Wild Animals. Dobson: The Presence of Peyer's Patches in the Cæcum and Colon of certain Mammals. Lockhart Gibson: The Invisible Blood-corpuscle of Norris. Marcus Gunn: The Eye of Ornithorhynchus Paradoxus. D'Arcy Thompson: On the Nature and Action of certain Ligaments. Ainslie Hollis: Researches into the Histology of the Central Grey Substance of the Spinal Cord, Medulla Oblongata, and Pons Varolii. A. Thomson: Varitions of the Thoracic Duct associated with Abnormal Arterial Distribution. W. Stirling: The Ferments or Enzymes of the Digestive Tract in Fishes. Walter Colman: The Minute Structure of the Spinal Cord of a Human Fœtus. Sheridan Delépine: Contributions to the Study of Nucleus Division.

Notes on Materia Medica and Pharmacy. By FREDERICK T. ROBERTS, M.D., B.Sc., F.R.C.P. London: H. K. Lewis. 1884.—Dr. Roberts points out that the duration of the course of lectures on materia medica required by the examining boards is so short that it is difficult to do justice to the whole subject. He has accordingly compiled these notes in the hope that their publication will in future enable him to devote his entire course to therapeutics. Much of the information is arranged in a tabular form, and seems well

Digitized by Google

adapted to the requirements of students preparing for examination.

Materia Medica, Physiological and Applied. Vol. I. London: Trübner and Co. 1884.—This is a work of over seven hundred pages devoted to a consideration of the action and uses of some half dozen remedies, including aconite, digitalis, nux vomica, and bichromate of potassium. The historical notes on aconite and the collection of cases of poisoning by aconitia will be read with interest.

Transactions of the Clinical Society, Vol. XVII. London: Longmans, Green, & Co.—The most important papers in this volume are:—Three Cases of Peritoneal Abscess in Children, by Dr. Goodhart; an Anomalous Case of Disseminated Cerebro-spinal Sclerosis, by Dr. Bastian; a Case of Spreading Obliterative Arteritis, by Mr. Pearce Gould, and a similar case by Dr. Hadden; a Case of Tuberculous Tumours of the Larynx, by Dr. Percy Kidd; a Remarkable Case of Tubercular Meningitis, by Dr. Angel Money; a Case of Gluteal Aneurysm, by Mr. G. R. Turner; Case of Acute Intestinal Obstruction caused by a Diverticulum and successfully treated by Abdominal Section, by Mr. H. H. Clutton; Multiple Abscesses of the Liver treated by Incision, with Recovery, by Dr. S. West; a Case of Dislocation Backwards of the First Lumbar Vertebra, which was successfully reduced under ether, by Mr. Davies-Colley.

Orthopædic Apparatus. By F. GUSTAV ERNST. Pp. 58. London: Sprague and Co. 1883. — This work consists of a series of illustrated plates, with corresponding descriptions of the various forms of mechanism employed in the treatment and cure of the numerous deformities of the human body, and the author has in it enabled a medical man readily to see what appliances are made for various deformities, and to determine which would be the most suitable for the case under his care. It is obvious that in such a manual as the one under notice it is impossible to represent every apparatus that may be found necessary for such deformity, every case having its own individual aspect; but it certainly contains a capital selection of modern instruments such as are daily recommended and used, and which form the base of all apparatus.

Christmas and New Year's Cards.—Messrs. BIRN BROS., Fine Art Publishers, of Milton-street, City, have submitted to us a packet of Christmas and New Year's cards, some of which are of distinctly novel design, whilst all are more or less remarkable for beauty and harmony of colour. We have also to acknowledge the receipt from Messrs. DAVIDSON BROTHERS of some very pretty specimens of the same class of publications, consisting of floral groups, coloured photographs, &c.

THE LATE DR. MAHOMED.

A MEETING was held on Dec. 10th at Guy's Hospital, Dr. Wilks, the senior physician, in the chair. In addition to many of the staff of Guy's, St. Mary's, and the Fever Hospitals, the following, and many others of those who sympathise with the movement, were present: Dr. Chadwick, Dr. Hare, Dr. Hughlings Jackson, Dr. Dyce Duckworth, Mr. Macnamara, the treasurer of Guy's Hospital, and Mr. Burdett.

Dr. Wilks having referred to the great loss sustained by the profession, explained how impossible it was for Dr. Mahomed, owing to his sudden and untimely death, to have made any provision for his wife and family.

The following resolution was next moved by Dr. Pavy and seconded by Mr. Field: "That a memorial fund be raised for the benefit of the widow and children of the late Dr. Mahomed."

Dr. Hare then proposed, and Mr. Aikin seconded, the following: "That a committee be formed to represent the staff of Guy's, St. Mary's and the Fever Hospitals, the University of Cambridge, the British Medical Association Collective Investigation, and personal friends."

The third resolution, proposed by Mr. Macnamara and seconded by Mr. Herbert Page, was to the effect that a circular letter be drawn up and issued by a subcommittee inviting subscriptions from all who have known Dr. Mahomed, or from those who have been in a position to appreciate his untiring energy in the furthering of scientific medicine. The members of this committee are Dr. Wilks (chairman), Mr. A. E. Durham (treasurer), Dr. Cayley, Mr. Field, Mr. Macnamara, with Dr. Goodhart and Mr. Jacobson as secretaries.

Strong and unanimous expressions of opinion were made to the effect that Dr. Mahomed deserved well of the profession; Mr. Burdett, while supporting the first resolution in sympathising terms, drew attention to this fact, and said that this was an occasion which called for special and strenuous efforts.

The following subscriptions, amounting to over £600, have been already promised or received:—

We are asked to state that subscriptions should be sent to Mr. Durham (treasurer), 82, Brook-street, W.; or to one of the secretaries, Dr. Goodhart, 25, Weymouth-street, W.; Mr. Jacobson, 41, Finsbury-square, E.C.

To the Editor of THE LANCET.

SIR,—I think your readers will be interested to read some of the many expressions of regret and sympathy at the death of the late Dr. Mahomed, which I have received from the members of the International Committee for Collective Investigation.

Professor d'Espine, of Geneva writes: "I hasten to express my sincere sympathy for the sad loss that you have just sustained in the person of Dr. Mahomed, whose eminent qualities I had an opportunity of appreciating at the Congress of London."

Professor Trier, of Copenhagen, writes: "With full and sincere sympathy I have received the information of the loss the profession of your country has sustained by the death of our excellent collegue. I beg you to receive the expression of my feelings on this occasion, and to communicate them to Sir William Gull and to Professor Humphry."

Professor Lepine, of Lyons, says: "I learn with the most lively sorrow the death of our colleague, Dr. Mahomed. I shall devote a few lines to him in the forthcoming number of the *Revue de Médecine*. Personally I am very grieved; for science it is a great loss, and for our committee as well."

Letters to similar effect I have received from Professors Ewald and Bernhardt, of Berlin; from Professor Bouchard, of Paris; and from Professor Lange, of Copenhagen.

I am, Sir, yours very truly,

December 10th, 1884. ISAMBARD OWEN.

THE SURGICAL AID SOCIETY.—From the report which was read at the twenty-second annual meeting of the friends and subscribers of this charity, on the 6th inst., it appears that during the past year 5357 patients have been relieved, comprising 1946 men, 2585 women, and 826 children. There was a total increase of 725 patients over the number relieved during the previous year, and this made an average of 103 per week. No less than 46,385 persons have been relieved since the foundation of the Society, and the number of surgical appliances supplied during the same period is 61,644, of which number 8101 have been supplied during the last twelve months. The total income during the year was £6380, and the expenditure amounted to £6310.

THE LANCET.

LONDON: SATURDAY, DECEMBER 13, 1884.

THE NON-MEDICAL DEGREES OF THE UNIVERSITY OF LONDON.

IN our last number we pointed out how little attention had been given by the Senate of the University of London to the suggestions of teachers in regard to medical studies and examinations, and how little hope there was, from the peculiar constitution of the Senate, of a remedy. The teachers in arts and science in our large colleges and schools are also greatly dissatisfied with the present position of their subjects in the University. When started in 1837 the University of London was merely an examining body, with power to grant degrees to certain affiliated colleges, such as University and King's, some other colleges for higher education, and the medical schools in London and the provinces. But this unimportant position as an examining board for these colleges and schools only did not satisfy the aspirations of the members of the Senate; they objected to be bound to teaching bodies, and so, on the experience of a short life of about twenty years, they determined to widen their portals, throw over the colleges and affiliated institutions, and give their degrees in Arts and Laws to any candidates who could pass the examinations, no matter whether they were taught or untaught. This step led to a large increase in numbers for the degrees, and private study appeared more and more frequently in the lists; but the professoriate were alienated, affiliation became a nonentity which might as well have been struck out of the Calendar, and most students, who were not debarred by pecuniary or religious objections, were now recommended by their teachers at affiliated institutions to proceed to the older universities. From that time, the representative pupils of many first-class schools and certain of the collegiate institutions have not presented themselves at the University, unless they felt sure of a monetary equivalent in the shape of a scholarship or exhibition, when their names might appear among the run of sectarian candidates and those taught privately. Since 1860, with only two exceptions, wranglers from Cambridge have taken the mathematical scholarship and gold medal at the B.A. Honours Examination. The University of London has kindly given £150 to the best mathematical student at Cambridge who will condescend to be examined and be styled University Scholar in Mathematics; and the Chancellor, as the representative of the Senate, is so pleased with this result that he almost always refers to it at the Commemoration as a singularly satisfactory feature in the University. The Matriculation Examination, "with its smattering of every subject and thoroughness in none," seems to be the *terminus ad quem*, and private tuition the main characteristic, in the non-medical faculties. At the end of 1883, 26,629 candidates had presented themselves for matriculation, 2696 (about 1 in 10) had obtained the B.A. degree, 1016 that of M.B., and 381, 523, and 11 those of science, laws, and music respectively, many of the latter being, of course, already Bachelors of Arts. Arts and Laws having been turned over to private study and private tuition, Science had, of course, to follow suit, and so when degrees in this faculty were instituted no course of training was laid down. Fortunately for students in science, laboratories are necessary for their instruction, and so, although this is ignored by the authorities of the University, they cannot escape from a certain amount of training under a professor or teacher. Professorial teaching, although reduced to a minimum, cannot be so absolutely divorced from the mere examination in Science, as is the case with Arts and Laws. Still, even now, on applying for an appointment, a young scientific man is more frequently asked where, for how long, and under whom he has studied his branch of the profession, than whether he has taken the B.Sc. Lond. degree. The inconsistency of the University authorities cannot be better shown than by their suspension of all regulations for non-medical degrees, and their rigid insistence on the stringent and unnecessary regulations laid down so minutely for candidates for the degrees in Medicine. Why do they not pursue their principles to a logical conclusion, and remove all restrictions except the examination test from the medical student also? The secret or avowed hostility of the best teachers in literary and scientific subjects to the examination and the system was merely a question of time after their sympathies had been thus alienated. Owens College, backed by the earnestness of Manchester in desiring a local, or, at any rate, a northern university, brought into more prominence the demerits of the University of London from the standpoints of arts, laws, and science, and now the promoters of a teaching University in London are closely following in its steps and for similar reasons. The teachers urge that their courses of study are cramped and made much less effective by the fact that another body, on which they are unrepresented, practically rules their curriculum; that this body lays down no reasonable plan for a suitable education, especially in the literary subjects, but picks out books and authors here and there in an irresponsible and unmethodical fashion, and that no one has any power to revise its omissions or commissions. Active professors are conspicuously absent from the Senate; the only representatives in arts and science who are at present engaged in teaching are Prof. HUXLEY, Dr. HIRST, Prof. WILLIAMSON, and Dr. ROUTH, and two of these have declared in favour of a teaching university. Can these be accepted as the only guiding spirits of a modern university and as an adequate representation of a professorial body such as the Senate ought to consist of? Even of these, only one really teaches at an affiliated college. The association of teachers with past and present examiners and the special committees of the Senate to form Boards of Studies, is the only method by which a proper governing body can be formed, one which will secure training by the best teachers, and uniformity of examination at a constant standard. Such a possible organisation seems to have hardly occurred to the authorities of the University of London, and hence a teaching university has become a possible alternative, and will, we suspect, prove a dangerous rival.

THE politicians are at length taking a leaf out of the book of the physicians, and trying consultation instead of contradiction. The change has not come a day too soon. The political engine had very nearly come to a deadlock, and

Digitized by Google

men of all creeds were beginning to feel disrespect, not to say contempt, for the discussion of public questions in a way that evoked from public men the rudest contradiction of all their opponents said, and resulted in a minimum amount of legislation, and much of this of the feeblest order. The flood of talk and the facilities for preventing the accomplishment of the most needed legislation, and that upon which there was the greatest consensus of opinion and desire, had really become intolerable. Parliamentary government itself seemed to be in danger. In no other sphere of work would such a system have been tolerated so long. Fancy it applied to the profession of medicine. Suppose Sir WILLIAM JENNER and Sir ANDREW CLARK, brought to the consideration of a case, to fall to and call each other names, and before and in the audience of the patient to denounce each other's suggestions, whether of diagnosis or treatment. The fate of an unhappy patient under such circumstances would be sealed; and not less disastrous would be the consequences to the name and fame of the profession. Some politicians, who care for their party more than for the State, are exhausting their energies in trying to demonstrate that all the credit of this new departure in politics rests with their particular leader, and all the advantages with their particular party. We take no such one-sided view of the matter. We give equal credit to Mr. GLADSTONE and Lord SALISBURY. We accord to both of them the discovery that things could not go on as they were, and that the interests of the State actually and urgently required that this system of contradiction should be controlled. It is to be assumed that Parliament is a body for the transaction of public business, then the precedent which has just been supplied in the fruitful interviews of the leading members of opposite parties will have to be much followed.

Our own observation of attempts at medical legislation has given us the worst opinion of the present system of governing. A subject upon which not a dozen members of either House can have any sound knowledge is thrown into the arena of discussion at the fag end of an August night. The will of the profession and the recommendations of a Royal Commission count for nothing. The hapless minister in charge is confronted with sixty or seventy trifling obstructive amendments, each of which can be spoken on indefinitely. A quasi-representative of the profession damns the measure with faint praise and in terms of apparent approval, and with many plausible platitudes, misleads the helpless House. This process has been gone through, not once, but five or six times in the last twelve or fifteen years, alike under Lord BEACONSFIELD and Mr. GLADSTONE, until everyone concerned, except the Bodies interested in the *status quo*, is disgusted and begins to think that any system of Government is better than the present. If there is any virtue in the new departure, for which Mr. GLADSTONE and Lord SALISBURY deserve equal praise, it will soon appear by the application of the new method to other or to all questions. A consultation of six intelligent and independent members from each side of the House would dispose of such a question as medical reform in the first week of the session.

Il Morgagni for October publishes a memoir on Nephrectomy by Dr. C. SPADARO, from which we gather that the operation has been performed in Italy ten times, with six recoveries. In Professor D'ANTONA'S last case, the clinical history of which is the basis of Dr. SPADARO'S communication, the patient, E. C——, aged thirty-four, had suffered from nephritic colic at various periods during the last ten years. The symptoms during the last eighteen months pointed to a purulent collection in the right kidney. On palpation the right flank was full and tender; the enlarged kidney extending upwards under the rib, downwards into the iliac fossa, and forwards to within two fingers' breadth of the median line. The surface of the tumour was equable and tense, but neither hard nor fluctuating. From long suffering the patient was anæmic and emaciated. Removal of the kidney having been resolved upon, as the only means of saving life, Professor D'ANTONA performed the operation on the 24th of April last. The right kidney having been exposed through the lumbar incision, a medium-sized trocar was pushed into the organ, and through it some ounces of exceedingly fetid pus were evacuated. In consequence of peri-capsular sclerosis the kidney was closely adherent to the surrounding tissues; and to facilitate enucleation the free extremity of the twelfth rib was broken and everted. The kidney and its capsule having been brought through the wound with necessary care, the pedicle proved to be short, thick, and hard. The artery and vein were included in one ligature, the ureter being tied separately; a third ligature beyond these included the whole pedicle, which was allowed to fall in, after the kidney had been detached, and PAQUELIN'S cautery applied to the free surface of the stump. The cavity was well dried, after being washed out with a 5 per cent. solution of sulpho-carbolate of zinc (*zinco solfo-fenato*). Two points of twisted suture were inserted in each angle of the wound; two drainage-tubes, free dusting with iodoform, and a bandage completed the dressing. The operation, which was performed under the carbolic spray, lasted an hour and a half. On section of the kidney, a large purulent cavity was found in its centre. The wound was dressed daily, but as it looked unhealthy and discharged fetid matter, the pedicle was exposed on the fifth day. As it was softened and had an offensive smell, a portion of it was removed, and the remainder treated with perchloride of iron. By the mouth and rectum every endeavour was made to nourish the patient, but he died from inanition on the tenth day after the operation.

Now that happily the cholera epidemic in Paris has almost died out, it seems advisable for us on this side of the Channel to see if we cannot learn some practical lessons from the experience of those who had to deal with it there. In the first place, it is clear that our arrangements must be all ready to hand. Though there is now no doubt that cases of true Asiatic cholera had occurred as far back as the first week in August, yet this was officially denied, and the outburst in November therefore came upon the authorities so suddenly that nothing was ready, and cases had to be dealt with as best they could. Secondly, the hospital accommodation was most imperfect. It was at first intended that there should be one hospital in the North and one in the South. It was, however, very soon found, as one would naturally expect, that this arrangement would not work. It was perfectly impossible to remove a patient suffering

Digitized by Google

from cholera for any distance without running a very serious risk of his dying in transit. This actually occurred in several cases, and the idea of using these two hospitals had to be abandoned. It was therefore necessary to set aside wards in every hospital in the neighbourhood of which there were any cases, and to isolate them as far as possible. This having to be done quickly, could not, of course, prove very satisfactory. It is not an easy matter at a short notice to completely "insulate" a portion of a general hospital, and to provide for a separate staff, administration, &c. Disinfection was found to be a very difficult matter to carry out efficiently. In cholera the evacuations are liable to be conveyed in all the clothing and bedding, and in addition to these the vomit, often ejected with great violence, is thrown upon walls, the ground, and the floor of rooms. The most thorough attempt to deal with the bedding and clothing was that adopted at the Hôpital de la Marimère, where a large vessel was provided in which the "infected" goods were boiled at a pressure much above that of the atmosphere. At the Hôpital St. Louis, where some wooden huts were used as cholera wards, an attempt, which proved partially successful, was made by Dr. LAILLY to burn the evacuations. They were first partly dried in a chamber at the top of a small stove, and finally thrown upon the fire itself. There seems no reason why this should not be far more efficiently carried out by receiving such of the evacuations as it is possible to collect in vessels containing charcoal. More charcoal could then be thrown on the top, and a more or less pasty mass would be formed which would be perfectly inoffensive, and could be placed directly in a small furnace, where the charcoal would materially assist in promoting its destruction. There would still, however, remain the evacuations which pass into the bedding and clothes, and these would have obviously to be dealt with specially. As regards treatment, there seems to be little if, indeed, anything new. In the stage of collapse it does not appear that any one remedy has been found to be efficacious, and the routine seems to have been simply to watch the case with a view to treating complications, while in the later stages the ordinary remedies were employed.

Annotations.

"Ne quid nimis."

THE ROYAL COLLEGE OF PHYSICIANS.

AN extraordinary Comitia of the College was held on the 9th inst., Sir W. Jenner, Bart., President, in the chair. In opening the proceedings the President made a feeling allusion to the loss sustained by the College in the death of Dr. Mahomed, and stated that Dr. J. F. Goodhart, the friend and colleague of the deceased Fellow, had consented to deliver the Bradshawe Lecture, for which Dr. Mahomed had been nominated. A communication was read from the General Medical Council requesting opinion on several important matters connected with the medical curriculum. It was referred to the Committee of Management for the Examining Board in England. Mr. Bowker, L.R.C.P. (before 1859) of New South Wales, having requested to be placed on the list of Members, his request was complied with. A report was read from the Committee of Management for the Examining Board in England, stating that arrangements had been made for commencing the scheme in January next, that the dates for holding examinations had been fixed, and synopses and schedules prepared. The committee proposed that candidates for the M.R.C.S. and L.R.C.P. who commenced study before Oct. 1st, 1884, should be admissible to further examinations under the new scheme, and that any who had passed the first or second examination at either College should be exempt from either of the examinations of the Board. The report and its recommendations were adopted. A report from the Finance Committee was also adopted. It referred, among other matters, to a proposal to procure a site on which to build examination rooms. Such a site was now available, convenient of access from either the College of Surgeons or the College of Physicians; and a Building Committee was nominated to confer with a committee of the former College upon the subject. An alteration of the bye-law relating to the appointment of examiners, rendered necessary by the formation of the new Board of Examiners, was proposed for the first time.

WELLINGTON COLLEGE.

THE recent melancholy occurrence at Wellington College of two deaths within a few days of each other—one that of a master, and the other of a pupil—has again brought prominently before the public the important question of the health of that great school. They both arose from diseases which are believed to have an intimate connexion with blood poisoning, and this cannot but give rise to a strong feeling that there is something wrong in the sanitary condition of the College or its surroundings. It will not be disputed, we presume, that it is the duty of the governors of a great institution like Wellington College to see not merely that the education of the pupils is of the best quality, but that due regard is paid also to their physical condition, and that all preventable sources of disease are removed. And on this point it appears to us that some evidence is required to prevent a charge of neglect being brought against the governors of Wellington College. At the end of last year their attention was called by the medical officer to the unsatisfactory state of health of the boys as evinced by the prevalence among them of disease of an apparently malarial type, in several instances of a severe and fatal character, and attributed by him chiefly to malaria arising from the want of subsoil drainage of the grounds surrounding the College—an opinion also held by Sir Wm. Gull. It is but fair to suppose that some steps were taken to remove, or at least ameliorate, the insanitary conditions which were thus brought under notice, but, so far as we are aware, no information has been afforded as to the measures then adopted. It would tend greatly to remove the fears which this recurrence of disease has not unnaturally excited in the minds of those having boys at the College if the governors would make known what steps they have taken and under whose advice they have acted, and if they would also furnish a numerical return showing what has been the state of health of the boys during the past year. But it is of still more importance that some guarantee should be given that the sanitary condition of the College and of the masters' houses shall be examined and reported upon by competent experts, and that the measures they may deem necessary will be carried into effect. To impart any value, however, to such a report, it is essential that it be made by persons conversant with sanitary work, and also independent of the College authorities. With this view it would be advisable on the part of the governors either to appoint a committee consisting of two medical men who have made sanitation their special study, and two first-class engineers; or, as we formerly suggested, to apply to the

Digitized by Google

Secretary of State for War to permit them to avail themselves of the services of the Army Sanitary Commission to make an exhaustive inquiry into the causes of these outbreaks of disease in the institution, and the means best adapted to obviate their recurrence. Unless some such course is adopted, and the cause of this morbific condition is fully investigated, it can hardly be doubted that the College will seriously suffer. The failure on the part of the governors to remove the cause of this prevalence of disease of a serious character indicates the necessity for some more searching inquiry than has yet been made into its nature. It would also be greatly to the advantage of the College if the suggestion we formerly made were adopted, that the medical element should be introduced into the governing body. One or more retired army medical officers who have made sanitation their study would be invaluable in keeping a watchful supervision over the health of the school, and advising their colleagues on all questions relating to the physical welfare of the boys.

"MORBID RELIGIOUS AFFECTION."

WE regret to have wounded the susceptibilities of our respected contemporary the *Tablet*, and because we are sincere in our regret, and because we do not for a moment question the sincerity of the organ of Catholic opinion, we can forgive the spirit in which the censor attacks and condemns us. We are "dogs," and "holy things" must not be exposed to us. The *odium theologicum* is as strong upon our contemporary as if he lived in the Middle Ages, and it is evidently fortunate for us that our lot has been cast in these more peaceful times. So distraught is the *Tablet* that it not only waxes wroth and calls names, but altogether mistakes both the facts and the arguments. This is how our contemporary delivers himself:—"It is not our intention to vindicate the use of the most sacred and most affecting of religious images. The reproach of the cross is as old as Christianity, and we are quite content to bear it; we desire nothing better." Now, nothing could possibly be further from our wish or thought than to condemn the use of "the cross" as a symbol or religious image. It was to the crucifix we took exception, and the "reproach of the cross" has nothing whatever to do with the matter. We will not yield place to the *Tablet* in respect for the idea symbolised or the symbol itself. We spoke not of use but of abuse; and if an Apostle could say, "If meat make my brother to offend, I will eat no flesh while the world standeth," it can scarcely have been "abominable" to ask the *Tablet* to disuse the crucifix, or in some way to control its use so as to prevent serious moral abuse, because it *is* a cause of offence, and very terrible offences too, on the part of too many who misuse it. What so grievously exasperates our contemporary and gives the acridity of extreme bitterness to his attack upon us is the inference that we must needs be disciples of "a brutal philosophy" and profess "materialism of the coarsest character," because we have remarked that "the mischief which results from thinking and speaking of the mind as something apart from the body, as more than brain function, cannot be over-estimated." We cannot expose to the writer in the *Tablet* unnecessarily scientific things. It would clearly be profane to do so. He is manifestly a philosopher who has so simply fixed his intellect on his own science as to have forgotten the existence of any other; and in this forgetfulness he is unable to perceive the difference between science and sentiment, fact and faith. We have not a word to say against any man's belief. Outside the known, there may be much that is knowable, as well as much that is unknown and unknowable, at present at least. We are *not* of those who dare to affirm a negative; to assert that because science is unable to recognise anything outside or behind organised matter there is nothing more. The scientist, as a scientist, must needs be agnostic. He has no place or right to question the elements or subjects of faith. There is nothing in the strictest science that forbids or prevents the exercise of faith. By faith a man may enter within the veil and live another life. His intellectual position is simply and logically that of the mathematician who lays aside the rigid methods and inexorable laws of his science to indulge in the pleasures of the imagination, or the laborious historian who turns from his severe study of facts to romance and poetry. We will go further, and admit that the intellectual nature requires imagination and romance and poetry for the perfect development of its parts. What we had to say, and must repeat, is that very great confusion and much mischief results from treating the mind as if it were not what it is—namely, brain-function, and that consequently the brain is reflexly influenced by particular descriptions of mental activity, and may be weakened and depraved by the cultivation of those ecstatic states which are supposed to be religious. We do not wish to wound the susceptibilities of our contemporary needlessly, or there is much that might be added to what has been already said in these columns; and we have reason to know that, if not the *Tablet*, high ecclesiastical authorities, to which even the *Tablet* would bow, have perceived the peril against which we have warned our readers, together with other besetting dangers whereto both the clergy and their flocks are exposed. We have no desire to lift the veil; we simply throw out the hint, and the warning having been given, the subject may, so far as we are concerned, be allowed to drop. Only this would we whisper in the ear of our contemporary, in all friendliness, *Prius quam incipias, consulto.....opus est.*

LECTURESHIP IN HUMAN ANATOMY, OXFORD UNIVERSITY.

THE delegates of the Common University Fund will shortly proceed to the election of a Lecturer in Human Anatomy. It will be the duty of the lecturer to lecture and to give instruction as demonstrator in conformity with the requirements of the Royal College of Surgeons and of the Examining Board for England, and he will be subject to any regulations which may be made by the delegates. The lecturer will receive a salary of £300 a year, and will not be entitled to take fees. He will be appointed for a period of five years, and will be capable of reappointment. He will not be allowed to engage in practice during his tenure of office. Candidates for the lectureship must hold the diploma of a College of Surgeons in Great Britain or Ireland. Preference will be given to candidates who have served in the office of demonstrator at an established medical school. Applications, endorsed "Lectureship in Anatomy," should be sent to the Secretary to the Delegates of the Common University Fund, New College, Oxford, not later than February 1st, 1885.

THE DIAGNOSIS OF GASTRIC DISEASE.

METHODS have been adopted from time to time with a view of determining the digestive activity of the gastric juice outside the body. Van der Velden elaborated a method for carrying out this plan by getting patients to swallow a dry sponge enveloped in a gelatinised capsule. Leube used to wash out the stomach with about 300 cubic centimetres of iced water. Recently M. Beaumetz has adopted the principle of aspiration in order to obtain some gastric juice. There appears to be no need for the practical physician to acquaint himself with the details of the procedure nor with the minutiæ of the apparatus concerned. Van der Velden said that in cancer of the stomach the secretion from this organ contained no hydrochloric acid, and thus believed that an easy way was open for him to

Digitized by Google

distinguish between cancer and other chronic gastric disorders. Leube concluded that the degree of acidity of the gastric juice would give us some idea of the degree of the dyspepsia, and he drew no other conclusion from his careful study of the subject. A certain colouring matter derived from coal tar, and known as orange-poirier No. 4 or tropeoline, undergoes a change to a clear violet-red tint when a one per cent. solution is brought in contact with muriatic acid, whilst it does not lose the yellow tint with lactic and other acids. This tropeoline has been employed in testing the condition of the gastric juice. The above information is interesting, but as yet cannot be said to possess any value for clinical medicine.

SMALL-POX IN LONDON AND OTHER LARGE ENGLISH TOWNS.

THE recrudescence of small-pox mortality in London is an undoubted fact, but, speaking generally, the prevalence of the disease in other parts of England and Wales is very slight and shows no sign of increase. The deaths from small-pox in London and its outer ring of suburban districts were respectively 69, 344, and 269 in the first three quarters of the year, and in the first ten weeks of the current quarter, ending the 6th inst. 346 fatal cases were registered. The weekly returns of the Metropolitan Asylum Small-pox Hospitals afford a valuable gauge of small-pox prevalence in the metropolis. At the beginning of this year only 100 cases of the disease were under treatment in these hospitals, but by the beginning of July they had increased to 1368, after which, under the influence of the hot weather, they steadily declined to 471 on Sept. 20th, increasing again slowly to 580 on Nov. 1st. During the following five weeks ending the 6th inst. a rapid increase occurred, and on the last-mentioned date the number of cases under treatment was 1027. In the twenty seven provincial towns dealt with in the Registrar-General's weekly return, and having an estimated aggregate population of nearly five millions of persons, no such increase of small-pox mortality has taken place, such mortality having steadily declined throughout the year. The deaths from small-pox in these twenty-seven towns were 145, 121, and 56 in the first three quarters of this year, and but 22 were recorded in the first ten weeks of the current quarter. According to the Registrar-General's last quarterly return, the whole country, except the metropolitan district, was unusually free from small-pox mortality up to the end of September. Since that date only one outbreak of small-pox has been noteworthy. This occurred at Durham, where 25 fatal cases were recorded during October and November.

ADULTERATION OF DRUGS.

ATTENTION is once again being called to the fact that our drugs are as a rule largely adulterated. From the returns of the public analysts it would appear that once in four times on an average a prescription made up at a chemist's shop is not compounded of pure drugs prepared in strict accordance with the directions of the British Pharmacopœia. One out of four, at all events, is the average of samples of drugs purchased by private individuals for analysis which are found to be adulterated; but as the authorities of the Local Government Board point out, it is probable that a purchaser's suspicions have been pretty strongly aroused before he goes to the trouble and expense of having the matter investigated. Of samples purchased indifferently by the officers appointed under the Adulteration Act the proportion is much smaller, being only one-seventh; but it is sufficiently large to suggest unpleasant reflections, when we take into consideration the importance to the patient of getting exactly what is prescribed for him by the physician. Many drugs are not only adulterated or "sophisticated," but have, in addition, undergone deterioration by exposure or long keeping. The result, as the Board points out, is "that a prescription compounded of such drugs may fail altogether to produce the effect which would have been produced by drugs of proper quality." In other cases preparations of expensive drugs are unduly diluted, or a cheaper drug is intentionally substituted. That these disgraceful practices exist, and that they are of common occurrence, is well known to every chemist. In the interests of the sick and suffering we feel bound to revert to the subject, and shall not hesitate to do so until legislative action is taken in the matter. Some four years ago Mr. C. Lewis Deehl presented a report to the American National Board of Health which is worthy of careful consideration. That paper deals with a great many questions, and concludes with certain suggestions for limiting the sale of so-called "patent medicines." It is shown that the most energetic agents of the materia medica enter into their composition, often in doses which no physician with any regard for the welfare of the patient would prescribe. These dangerous doses are necessary to produce the decided and prompt manifestion on which much of their popularity depends. It is a subject for congratulation that these crying evils will before long receive attention at the hands of the Government.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE subject of the tubercular bacillus has at length been brought before the notice of our leading Medical Society. A paper, based upon a most extensive and laborious research of the lesions of phthisis, with especial reference to the presence and distribution of the bacilli, was communicated by Dr. Percy Kidd on the 9th inst., and gave rise to a discussion which will doubtless be extended over the whole of the next meeting. For we cannot agree with one of the speakers that the debate should be strictly limited to the subject of the paper. It is impossible to avoid the wider bearings of the question, such as was attempted by Dr. Creighton, whose remarks implied a belief that "rod-shaped organisms" find in tubercle and in the allied infective "granulomata" a favourable nidus for their development. It was a bold thing for him to criticise as he did Professor Koch's procedure, for the wide reputation obtained by Koch is based upon his singular care and foresight in all his experiments. Dr. Creighton's contention that Koch, by the method he employed, did not prevent the introduction into his culture tubes of tubercular virus, apart from the micro-organisms, will, we hope, be met by those who have practically worked at the subject. It is of course the keystone of the whole matter as regards the proof or disproof of the specific character of the bacillus and its causal relation to tuberculosis. Besides this question, the points raised by Sir A. Clark respecting the nature of pneumonic and fibroid phthisis will open up ground for debate, which certainly could not have been exhaustively treated by prolonging the meeting last Tuesday. We may, then, anticipate a thorough discussion of these important pathological questions at the next meeting, and will reserve any further comment until that has taken place.

LOVE OF LIFE AS A DEFENCE OF CANNIBALISM.

IT would have been a bad day for the fame of English law, and a worse one for the rare fame of British sailors, if any other verdict than one of unmistakable murder had been delivered in the High Court of Justice in the case of the Queen *v.* Dudley and another, of the *Mignonette*, for killing, for the purpose of preserving their own lives, the cabin-boy without drawing lots and without his consent. Life on the high seas is surely full enough of terrors and hardships. To add to these the dread that in extremities the weakest and the youngest will be liable to be sacrificed to appease the hunger

Digitized by Google

and thirst of those whose glory it has always been to protect them in their helplessness, will be to make new demands on human hardihood—even the hardihood of one who

"Nec timuit præcipitem Africum
Decertantem Aquilonibus,
Nec tristes Hyadas, nec rabiem Noti."

We are not insensible to the sufferings of Captain Dudley and his companions. But we are none the less of opinion that their act was at once a capital crime and a deep blot on the humanity and pity of the class to which they belong, which stands out in the history of this nation and of all nations for its unselfishness, its endurance, and its consideration for the weakest even when the storm is at its worst.

THE OBSTETRIC DEPARTMENT OF THE QUEEN'S HOSPITAL, BIRMINGHAM.

THE resignation of Mr. John Clay, after a full term of active service, has placed the authorities of the Queen's Hospital in an awkward position as to the appointment of a fit successor in this important department. The committee, in view of the more perfect filling up of the vacancy, resolved to disconnect the obstetric duties of the department from the work of operating, the holder of the former office having charge of the out-patients and the midwifery, while the incumbent of the latter was to have the beds and do the operations of abdominal section. With this object before them they ascertained the willingness of the senior surgeon to the Hospital for Women to take the more responsible appointment, and called a meeting to alter the laws in accordance with their purpose. In the meantime the authorities of the Hospital for Women made it known to their senior surgeon that his election to this post would involve the probable loss of the one he at present held in connexion with their institution. This led to a correspondence in the *Birmingham Daily Post* on certain matters which it seems inadvisable to discuss in the general press, between the chairman of the Medical Committee of the Queen's Hospital on the one hand, and one of the surgeons of the Hospital for Women on the other. The outcome of this has been that the Queen's Hospital authorities have called another meeting, in which they have rescinded the law passed a short time since, and have resolved to fill up the junior vacancy only at present. It seems that there is no law at the Hospital for Women to prevent any of its officers holding an appointment at another hospital, but it is said that steps will be taken to pass one to this effect at the annual meeting of governors. In the meantime we see an unedifying spectacle—the authorities of one hospital apparently stultifying themselves in the passing and rescinding of a law to serve a particular purpose, whilst the authorities of the other hospital assume a position equally illiberal in bringing pressure to bear upon one of its officers to prevent him from exercising his judgment in the acceptance of duty in another hospital. In either case the position is a disagreeable one, and not conducive to the interests of the profession or the public.

QUEBEC LUNATIC ASYLUMS.

IT is satisfactory to learn that the damaging report made by Dr. Hack Tuke on the lunatic asylums of the province of Quebec have been fully endorsed by the Medico-Chirurgical Society of Montreal, which at a recent meeting passed a series of resolutions in support of his statements. A hope may be expressed that a thorough investigation of the system of management of the insane poor in this province may follow, and may result in the establishment in the lunatic asylums of the authority of the physicians, whose influence has hitherto been powerless to prevent the existence of the abuses which Dr. Tuke has brought to light.

THE HAMPSTEAD HOSPITAL CASE.

THE agitation against the Hampstead Hospital was the first protest which was made against the establishment of centres of small-pox in populous localities, and the continuance of the protest is evidently based upon a conviction that the present small-pox hospital in that locality is a distinct source of danger to the health of those living in its vicinity. The Metropolitan Asylums Board, in their anxiety to carry out their functions in such a way as not to raise opposition, have materially reduced the number of small-pox patients at each metropolitan centre, and it yet remains to be seen what will be the total outcome of this new departure. That its sufficiency is looked upon with suspicion seems evident from the renewed inquiry which the Local Government Board have instituted with regard to the Western District Hospital, Fulham; and, unless we are very much mistaken, the decision of Mr. Justice Pearson in the case of Fleet *versus* the Managers, will, notwithstanding the fact that it was in favour of the defendants, give a decided impetus to the opposition which already exists against isolation hospitals for small-pox inside the metropolis. That judgment drew a line between small-pox hospitals in such a place as London and similar institutions in country districts, and the Judge expressed a strong conviction that when there is an epidemic of small-pox in London, there is a special increase of the disease in the neighbourhood of small-pox hospitals. This has, of course, been conclusively proved as regards both Fulham and Homerton, and in consequence of this proof great efforts have been made in order to prevent such extensions in the future; especially have efforts been made to avoid mischief from ambulances and otherwise along the lines of traffic. It is, therefore, to recent experience that we must mainly look, and at the trial adverted to the evidence went to show that notwithstanding all these changes the establishment of a small-pox hospital in London means the radiation of the infection to the area around. Dr. Gwynn of Hampstead has indeed shown that so recently as during the present year the small-pox mortality in the vicinity of the Hampstead Hospital has been about ten times as great as in the parish as a whole. We believe the dissemination of the poison to be aerial, but it is a matter of indifference to the people affected whether it comes in one way or another. The contention of the Hampstead people is that the mischief remains much as it has always been since the small-pox centre was established in their midst; and so far the evidence seems to be strongly in favour of their contention.

THE AMBULANCE SERVICE IN PARIS.

THE service for disinfecting premises and for removing patients after cases of cholera in Paris has been organised, so far as the intervention of the public authorities is concerned, by M. Besançon, chief of the Second Bureau at the Prefecture of Police. This gentleman is also entrusted with the management of the fire brigade and other public services of a similar description. Dr. Dujardin-Beaumetz, with the assistance of Prof. Pasteur and many other eminent medical men, conducted a series of experiments at the Cochin Hospital; and, having concluded in favour of disinfection by means of sulphuric acid gas, M. Besançon was called upon to carry out the instructions of the Council of Hygiene in this respect. With great difficulty he secured the services of a few men as public disinfectors, to whom comparatively high wages had to be paid. The medical men, however, who in different districts of Paris lent their aid, had very responsible duties imposed upon them, for which they received no sort of remuneration. At all hours of the day and night these voluntary medical officers were called upon to visit suspicious cases, and decide whether removal to the hospital and disinfection were necessary. It is only within the last

Digitized by Google

two years that special means of conveying infectious cases to the hospital have been organised in Paris; and these, for a population exceeding two millions, consisted of not more than five ambulance carriages. Of course this provision proved utterly inadequate when cholera broke out, and we have just been informed by M. Besançon that the number of ambulance carriages has now been raised to forty. The cold weather necessitated the installation of a warming apparatus in each of these conveyances, and blankets had also to be found. We trust that this service, hastily extemporised in view of the cholera, will be maintained as a permanent institution, and that the medical men who have so generously volunteered their services in a moment of exceptional danger will be offered a permanent position and an adequate stipend as medical officers of health in their respective districts. Without any special epidemic, forty ambulance carriages are not too many to meet the requirements of a population as large as that of Paris, if the practice of isolation in cases of infectious diseases became more general. We trust also that the disinfecting corps will not be allowed to disband, but that they will now be employed to purify houses where other diseases besides cholera could be stamped out by energetic action. If this be done, the cholera epidemic will not have visited Paris in vain, and in the long run the result will show an economy rather than a loss of human life.

THE MILLER MEMORIAL HOSPITAL.

WE stated last week that this hospital will be formally opened at Greenwich on the 17th inst. It has been founded to commemorate the late Canon Miller's connexion with Hospital Sunday; and the opening ceremony will be performed by the Lord Mayor as President of the Fund. This is the first hospital built on the circular system which has yet been opened, and additional interest attaches to it from the fact that Greenwich is the first of the metropolitan boroughs which has yet attempted to provide hospital accommodation for the poor who reside within the borough boundaries. At a meeting of the committee held on Tuesday last, to the great credit of the gentlemen composing that body, it was almost unanimously decided that the hospital should, if possible, be self-contained, and that the honorary surgeons should be Fellows by Examination of the Royal College of Surgeons of London or Dublin, or graduates in Surgery of a British or Irish university. South-east London has, therefore, determined to encourage members of the profession with the highest surgical attainments to reside in that district, and from the outset there should be no difficulty in filling up the three surgeoncies from amongst those who reside within two miles of the hospital, although the Committee have wisely provided that one of the surgeons may come from a distance.

INVALID KITCHENS.

A FORTNIGHT ago we referred to a project for the institution of invalid hotels for the accommodation of strangers during illness, and explained the circumstances and conditions under which we should consider such establishments most likely to work with profit to their owners and with benefit to the general and professional public. Following in the footsteps of this scheme comes another under the auspices of Lord Brabazon, which is certainly not less worthy of support—namely, one for the formation of invalid kitchens. It need hardly be said that these are intended to meet the wants of the sick poor only. They constitute an extension and improvement in medical treatment on the lines of the convalescent fund, now a well-known feature in the working arrangements of our hospitals and dispensaries. It is rightly urged in their support that many of the patients attending the hospital waiting-room need food in a digestible and palatable form infinitely more than medicine, while others require it not less as giving that constitutional purchase in support of medicinal treatment without the aid of which the latter may be lavished without result. The kitchens are to be placed in the neighbourhood of the various hospitals, and the certificate of one of the physicians to the effect that a patient requires invalid diet will enable him, if his case be found in other respects to be one for charitable relief, to have such food as he needs daily for a time in his own home. A small sum will be charged wherever the applicant is not too destitute. The proposed measure, if well supported and discreetly executed, will do much to remove a difficulty which has long been felt to forbid the full result of medical skill amongst the poor, and with which probably no hospital machinery will ever be able to cope with the same effect as outside voluntary effort. Contributions in aid of this deserving object may be sent to Miss Nicholson, the honorary secretary, 15, William-street, Albert-gate, S.W.

MEDICAL CHARGES AND DEATH CERTIFICATES.

THE papers have contained somewhat lengthy reports of an inquest on the body of Emily Sarah Harding, aged eighty-one, an old lady, with a limited income, who lodged at 9, Ormond-road, Hornsey-rise, and who before her death was attended for two days by Mr. Henry Foster Burnes, who called Dr. Wight into consultation. The old lady was of penurious and somewhat dirty habits, kept herself to herself, as such old ladies are apt to do till they drift into very dreadful states. In this case there was, according to Dr. Wight, a very debilitated and filthy condition with bedsores. A good inquest into the way in which she came to drift into that state would have been of public interest, and would have illustrated a large number of similar cases. But the inquest took another shape, and not unnaturally. It arose from some hitch in the granting of the certificate by Mr. Burnes. According to the nephew of the lady Mr. Burnes demanded thirty guineas as a condition of giving the certificate, enforcing his demand by telling the nephew that "otherwise an inquest would be held, which would be published in every paper in the kingdom." According to Mr. Burnes he only objected to give the certificate because the nephew did not know his aunt's exact age, and the thirty guineas were a charge which he considered "trifling" for his two days' attendance. It is rare to find a general practitioner in these days of low charges appraising his services at fifteen guineas a day! The jury seemed to find a sort of threat in Mr. Burnes's terms, and passed the following verdict:—"That the deceased died from exhaustion and old age, following extensive bedsores and partial paralysis;" adding, "We are further of opinion that the certificate of death should have been given by Mr. Burnes quite independently of the question of his medical charges. We sympathise with Mr. Harding, nephew of the deceased, and find that in every way he acted rightly and properly." As the coroner rightly pointed out, the jury had nothing to do with any dispute about medical charges between Mr. Burnes and Mr. Harding, but the demand for unusually large fees before giving a certificate was, to say the least, unfortunate, and requires explanation. Mr. Burnes must know that for this sum the old bedridden woman might have had the services of two or three skilled nurses and two or three leading consultants. We think that Mr. Burnes ought to have an opportunity of defending his conduct before the profession, though, by the way, his name does not appear in the Medical Register. It would not have been at all unreasonable

Digitized by Google

to have refused a certificate and to have demanded an inquest in such circumstances; but on his own showing he did not make this stand, but introduced money considerations, which have scandalised the public not a little and placed the medical profession in a questionable light.

PROFESSOR TYNDALL ON THE GERM THEORY OF DISEASE.

THE distribution of prizes to the successful students of the Harris Institute, Preston, was the occasion of an address by Professor Tyndall on three chief principles of modern science. The doctrine of evolution, the principle of the conservation of energy, and the germ theory of epidemic disease were the important topics on which Professor Tyndall dwelt with all his well-known powers of oratory and exposition. Of Professor Tyndall's right to discuss all these principles of science we can make not the least objection, but whether his complete acceptance of the views implied in the germ theory of disease may be regarded as a matter for congratulation or not is possibly open to doubt. But it is hardly consonant with what is really known on the matter to assert absolutely that the germ theory is proved for all the diseases which the Professor passed under review. We need only add that no new light was thrown on the question.

MILITARY HYGIENE.

A YEARLY report is issued by Dr. W. Roth which is unquestionably a valuable collection of materials bearing on the subject of sanitation amongst the armies of all countries. The current volume of the "Jahresbericht über die Leistungen und Fortschritte auf dem gebiete des Militär-Sanitätswesen" contains much that is of interest to epidemiologists as well as to general physicians. Taking some of this interesting information almost at random, we find, for example, that an epidemic of mumps was reported by Guasco to have happened at Toulouse. The local symptoms generally appeared towards the termination of the illness; the fever did not go beyond 39° C., and lasted no longer than twenty-four hours. In a fifth of the cases orchitis came on, and then the temperature rose in from twelve to twenty-four hours to 39° or 40° C.; the temperature remained at this height with marked morning remissions for from three to five days. After the swelling of the testicle had reached its height the temperature sank in from two to four days to the normal.

GEORGE SMITH OF COALVILLE.

REWARD for service done is a standing principle of equity. It does not necessarily follow, however, that the reward is proportionate to the service. It cannot always be said, indeed, that the principle itself has been honoured in the acts of those who ostensibly administered it. The kind of service which receives the highest common encouragement is usually that which we describe as interested; it is done as a matter of trade profit and for the sake of its return to the doer, not so much on account of conscience or for its yield to the general good. Perhaps it is even done unconsciously, as it often is done quite selfishly. On the other hand, the discoverer, the reformer of abuses, the educator, and the liberator, laborious as they are in great measure or entirely disinterested, have often had to work for no visible gain to themselves, or it may be only for hazard and injury. The world about them is all for its tangible profit, as far as it understands it; it has all along been content to move chiefly by the blind interlocking of circumstances; it considers, as little as it may, causes, reasons, intrinsic truth, justice, and ideas generally, whether right or not. With this material eye it has lately looked upon the faithful service of a far-sighted and far from idle man more wise for others' benefit than his own advantage. On professional and public grounds we regret to learn that neglect has overclouded the generous efforts of Mr. George Smith of Coalville. Of him it may be said that the Brickyards and Canal Boats Acts are his work. By them many thousand children have been lifted out of a cruel drudgery into liberty and intelligence. His service therefore has been patriotic and practical. It has no doubt been the aid rendered by an irregular to the Legislature. Still it represents good, valid, and directly political work. Yet he is destitute. The State, for reasons unexplained, has not rewarded him with the oversight of his work. Nothing has been given him but a sum sufficient for temporary relief out of the Royal Bounty Fund. An application that he should be placed on the Civil List was made some years ago, but it would seem to have been so languidly pressed by its supporters that its importance was not recognised. Now we learn that the *Pall Mall Gazette* has taken up the matter, and receives subscriptions towards a testimonial fund in aid of this unselfish benefactor. We may surely expect that the Government will, on their part, not fail to requite the services of a valuable auxiliary by a suitable and sufficient remuneration from the civil fund or otherwise.

THE CHOLERA COMMISSION.

IT is announced that Drs. Klein and Gibbes have presented a preliminary report upon their investigations into cholera, which are said to be "altogether subversive of Dr. Koch's theory." The comma bacillus was not found in all cases of cholera, and never in the blood or tissues; and stress is laid upon the failure to inoculate the lower animals. We must await the publication of the full report before attempting to contrast its statements with those of Dr. Koch. It may be remembered that success has been obtained by Nicati and Rietsch and by Koch in transmitting the disease by the direct introduction of cultures of the bacillus into the duodenum; and it will be interesting to learn whether similar experiments were made by Drs. Klein and Gibbes.

DEATH AFTER REMOVAL OF THE LARYNX.

THE patient whose larynx Mr. Jordan Lloyd removed at the Queen's Hospital, Birmingham, on the 22nd ult., and whose favourable progress was noticed in these columns, had a normal temperature, and was perfectly comfortable, in the evening of the 26th. Unfavourable symptoms then set in, the temperature rose rapidly to 102°, and death ensued from pneumonia on the sixth day after the operation. The condition of the wound was throughout most satisfactory. Thirty ounces of milk were injected into the stomach morning and evening through an elastic tube, and every four hours an enema consisting of half an ounce of brandy and three ounces of milk was administered.

EXPERIMENTAL THYROIDECTOMY.

WHILST the subject of the relations of the thyroid gland to myxœdema and allied affections is attracting so much attention both at home and abroad, it will be useful to give an abstract of the results of a series of experiments performed by Schiff, who is one of the foremost workers in this field of inquiry. All the animals from which the thyroid gland had been removed died within from four to twenty-seven days after the operation; and those animals that survived more than sixteen days died after the wound had completely healed. Somnolence and indifference, slowness and hesitation of volitional movements, fibrillar contractions of the muscles, alteration of the respiratory rhythm (so-called

Digitized by Google

respiration cardiaque), sensations of itching of the skin, and diminution or disappearance of tactile sensation, were the chief phenomena observed. The excitable area of the brain did not react to the most powerful galvanic stimulation. As death approached the arterial blood-pressure underwent an extraordinary fall owing to the dilatation of bloodvessels. The muscular tremors disappeared on section of the motor nerves supplying the affected muscles. The symptoms observed in different animals varied considerably. Schiff has concluded that the thyroid gland exercises a great influence over the nutrition of the central nervous system.

A "LUNATIC" KILLED (?).

WE trust the Commissioners in Lunacy will be competent and willing to sift to the bottom a very serious case of manslaughter which the medical superintendent of the Kent County Lunatic Asylum, at Barming-heath, Maidstone, has brought under the notice of the authorities, and which the Greenwich Board of Guardians has referred to the Commissioners. A man was arrested by the police on account of "extraordinary conduct in his own house," and subsequently, strapped down and sent to the asylum, where he was placed in a strait-waistcoat and confined in a padded room. He died, and *after death* it became known that his breastbone and certain ribs were fractured. The inquiry now to be instituted is to ascertain when, by whom, and how these injuries were inflicted. The need of a searching scrutiny is evident. The investigation must not be either carelessly or only formally carried out.

A MEDICAL SOCIETY IN HARROGATE.

WE are glad to notice that a Medical Society has been established in Harrogate. The first meeting took place on the 27th inst. at the Prospect Hotel. It was opened with an inaugural address by Dr. Myrtle, President. The address was followed by a paper read by Dr. John Gordon Black. After an animated discussion the members partook of supper, and dispersed, feeling that a step had been taken towards the establishment of kindly feeling and professional and scientific intercourse.

THE HEALTH OFFICERSHIP TO NOTTINGHAM.

IN the annotation on this subject which appeared in our last issue we inadvertently omitted the names of Dr. A. Campbell Munro, M.B., D.S.C. (in the Department of Public Health), M.R.C.P.E., C.M.Edin., Medical Officer of Health for South Shields and Jarrow-on-Tyne; and Dr. R. Bryden Hill, M.D., L.R.C.S.E., B.Sc. Edin., S.Sc. C. Camb., Medical Officer of Health for Oldham, who, in addition to those mentioned last week, are candidates for the vacant post.

THE COST OF THE MEDICAL COUNCIL.

THE last meeting of the Medical Council may be reckoned to have cost the profession £1650. This is rather a big sum to pay a body for *not* doing the work of supervising medical education and examinations.

THE BACTERIA OF THE MOUTH.

WRITING in the *Deutsche Med. Wochenschrift* (Nov. 27th), W. D. Miller claims that in 1882 he described the curved bacilli in the buccal mucus to which Dr. T. R. Lewis has drawn attention as resembling the comma bacillus, and he contributes further particulars concerning the various bacterial organisms found in this region and in the alimentary canal. The curved bacilli and spirochaete forms he has been unable to cultivate in various media, and therefore they do not resemble in all respects the comma bacillus. Another organism is one which occurs in the form of short plump rods, often in pairs, and it grows rapidly in gelatine. Another variety is curved, and by the conjunction of two or more individuals produces S-shaped or circular forms. This organism never produces spores, and grows very slowly in gelatine.

CONFECTIONERS AS DRUGGISTS.

AN "accident," which might easily have become a great disaster, has occurred at Chester, in consequence of the manufacture of cough lozenges by confectioners. Obviously makers of sweetmeats ought not also to compound dangerous drugs. In this case the cough lozenges contained morphia, and many children were poisoned by eating of the contents of a bag stolen by some boys. Happily none of the cases proved fatal.

PROFESSOR MARIANO SEMMOLA, the distinguished representative of the Neapolitan Medical School and also of the city of Naples in the Italian Parliament, having communicated to the Academy of Medicine in Paris a monograph, "Sulla cura fisiologica del Colera" (on the Physiological Cure of Cholera), Professor Dujardin made it the subject of a lecture at the Hôpital Cochin, and maintained that of the various methods of treating cholera Dr. Semmola's had yielded the most satisfactory results.

IT is stated that a young physician in Vienna, accused of the unscientific treatment of a sore finger, was recently fined and sentenced to repeat his examinations. His appeal against the verdict was passed on to the College of Physicians; but the unfortunate man, without waiting for the final decision, committed suicide by drowning himself in the Danube. The College of Physicians, after inquiry, decided that his treatment had not caused the loss of the finger, and the High Court acquitted him.

AT a recent meeting of the Anatomical Society of Paris M. Babés read a short paper (*Progrès Médical*, Dec. 6th) on the comma bacillus in cholera, based on observations made in M. Cornil's laboratory from material obtained during the recent epidemic. His observations, which relate to the morphology of the bacillus and its behaviour in cultivation, are for the most part confirmatory of those of Koch. He did not succeed in finding the bacillus elsewhere than in the intestine.

NOTHING is as yet known respecting the appointment of a successor to the late Sir Alexander Grant. Several names have, however, been mentioned in connexion with the vacant office, amongst them being those of Professor Maclagan, Turner, Campbell Fraser, Calderwood, Thomson, Sir William Thomson, Sir Alexander Christison, Principal Tulloch and Sir Lyon Playfair, the latter of whom, however, stated, declines to come forward.

ON the 9th inst., Sir Charles Dilke attended the meeting of the Chelsea Vestry, of which he is a member, and asked the Honourable Conrad Dillon permission to state that the Local Government Board were pledged to appoint a committee on the subject of overhead wires, and that it was hoped that on the report of that committee a Bill would be brought in by the Government early next session.

DR. G. S. ROY, Professor of Physiology in the University of Cambridge, has been admitted to the degree of M.A. Camb., *honoris causâ*.

Digitized by Google

A MEETING of the present and past students of the London Hospital will be held in the College Library on Tuesday next the 16th inst., at 1.15 P.M., to consider what steps should be taken towards making some presentation to Mr. James E. Adams on his retirement from the staff of the hospital through ill-health. Dr. Stephen Mackenzie will preside.

THE Broca prize of the Anthropological Society of Paris has been awarded to Dr. Leo Testut of Lille for his work entitled "Muscular Anomalies in Man explained by Comparative Anatomy; their importance in Anthropology."

THE QUEEN has been pleased to confer the honour of knighthood on Henry Enfield Roscoe, Esq., LL.D. (Cambridge and Dublin), F.R.S., Professor of Chemistry in the Victoria University, Manchester.

OUR American exchanges announce the death of Dr. Samuel Bemiss, Professor of the Theory and Practice of Medicine and of Clinical Medicine in the University of Louisiana, aged sixty-three.

THE second and final report of the Royal Commission on Metropolitan Sewage Discharge has just been issued, and will receive attention at our hands next week.

DR. LESLIE OGILVIE has been appointed Physician to the Royal Academy of Music.

SMALL-POX is stated to be spreading with rapidity in Sydney.

THE man from whose brain Mr. Godlee recently removed a tumour continues to make satisfactory progress.

COCA AND COCAINE.

THE alkaloid cocaine was produced by Niemann in 1860 from the leaves of the Erythroxylon coca. Professor Schroff was probably the first to mention the fact of its anæsthetising effect on the mucous membrane of the tongue. The credit of rescuing cocaine from the oblivion into which it had fallen, and of giving it a practical application, unquestionably belongs to Koller, as was first announced in this country by THE LANCET of Oct. 4th. The next occasion of its public appearance was given in THE LANCET of Oct. 18th in the report of the Ophthalmological Society, where Messrs. Benson, Marcus Gunn, and Nettleship spoke of its use in ophthalmic surgery. Since that time cocaine has by a bound leaped into professional favour. The great excellences of cocaine consist in the limitation of its action to the tissues to which it is applied. No doubt other symptoms at a distance do result from the external application of the anæsthetic, but they are for the most part insignificant and by no means dangerous. In some measure cocaine may be compared with curare. The one agent paralyses the termination of the sensory nerves, whilst the other paralyses the termination of the motor nerves. Aconite would seem to act in a manner the very reverse of cocaine. The contemplation of a few facts of this kind leads one to think of the Ultima Thule of anæsthetics as likely to be not one of the least splendid triumphs of science. During the past few weeks we have published numerous letters bearing on the question, and we must refer our readers to those stepping-stones in the development of the usefulness of cocaine. Last week we published Koller's paper, which was read on October 17th at the meeting of the Vienna Royal Imperial Society of Physicians. No doubt much remains to be worked at before the full value is given to this latest addition to our armamentaria, and before a full explanation of the mode of action of the drug in the one particular respect for which it is in so great demand can be given.

Coca leaves are the produce of Erythroxylon coca, Lamarck, a shrub cultivated on the slopes of the Cordilleras of Boliva, Peru, and Columbia. The Spanish conquerors of Western South America became well acquainted with the use of coca by the aboriginal Indians. Nicolas Monardes, a Spanish physician, published at Seville in 1565,[1] a History of Medicinal Simples brought from the New World, in which he gives a description, obtained from the commentaries of Pedro Cieça and others, of coca leaves, their mode of collection and drying, and states they were their most important article of commerce, being used for barter or exchange in place of money among the South American Indians. He also describes their use of coca as being threefold. (1) It was chewed and mixed with the powder of calcined shells of oysters and other shellfish; this paste after being allowed to ferment was formed into boluses or troches, and dried; during long journeys these boluses were sucked, and under their influence hunger and thirst were alleviated and bodily strength was sustained. (2) When eaten for producing pleasure or intoxication the coca was chewed by itself; and (3) it was mixed with tobacco and smoked. Among others the following travellers have written on coca: Pöppig, Weddell, and Markham; of pharmacologists, Quincy, Pereira, and Hanbury do not mention it, nor has it been official till the last French Codex and United States Pharmacopœia. As a theme for the poet, Milton, who drew many of his similes from tropical plants and scenery, appears not to have known of it, as he does not mention it. Cowley, later, thus writes:

> "Our Varicocha first his Coca sent,
> Endow'd with leaves of wondrous nourishment,
> Whose juice suck'd in, and to the stomach ta'en,
> Long hunger and long labour can sustain;
> From which our faint and weary bodies find
> More succour, more they cheer the drooping mind,
> Than can your Bacchus and your Ceres join'd.
> Three leaves supply for six days' march afford;
> The Quitoita with this provision stor'd,
> Can pass the vast and cloudy Andes o'er."

The coca shrub grows to a height of from four to eight feet, and resembles our blackthorn in appearance. It has small white, short-stalked, drooping flowers, in clusters upon the branches in places where the leaves have fallen. The leaves are closely placed, alternate, about two inches long, oval oblong, entire at the margin; sometimes they are acute but usually blunt and emarginate, with a small apiculus in the notch at the apex, rather thin but opaque, smooth with a prominent midrib, and on each side a curved line running from the base to the apex, showing its mode of vernation. When fresh the upper surface is bright dark-green in colour, the lower is paler and strongly marked with veins. The carefully dried leaves have the odour of tea, but if dried less perfectly they have a bouquet of their own which is very unpleasant in the breath of those who chew it. They have a somewhat aromatic and bitter taste, and are more active when freshly dried. By permission we have tasted a fresh leaf in the Botanic Gardens, and the benumbing effect on the tongue—dulling its sensibility—was apparently much greater than that of a number of dried leaves.

The plants are raised from seeds, and the cultivation, at an elevation of from 2000 ft. to 7000 ft. above the sea level, is carried on with great care, as described by Dr. Weddell, who supposes the name *coca* to be derived from an Indian term signifying *the* tree or plant. Its original habitat is doubtful. It has been acclimatised in Ceylon. Botanical specimens were first sent by Joseph de Jussieu to his brother in 1750; these Antoine-Laurent de Jussieu referred to the genus Erythroxylon, and finally they served as types for Lamarck to give the plant his designation "Erythroxylon Coca" in his "Encyclopédie." The coca shrub yields three or four crops of leaves annually, from the age of eighteen months to forty years. The produce has been estimated at from thirty to forty million pounds yearly. Its value on the spot varies from amounts equal to from one to five shillings per pound English. The most productive plantations, or "cocals," are in the province of La Paz in Bolivia, but our principal imports come from Lima.

Coca was used in the religious rites of the Incas; it was by them treated with great reverence, and by their conquerors with some superstition. A Council of Bishops at Lima in 1569 condemned its use, and stated that the belief entertained by the Indians that the habit of chewing coca gave

[1] A Latin translation, by Carolus Clusius, published at Antwerp 1582, 8vo, is in the library of the Medico-Chirurgical Society.

Digitized by Google

them strength was an illusion of the devil. By the Indians working as miners or at other occupations, coca is still chewed with a paste made of the ashes of certain plants or with lime. They become more or less slaves to the habit; opinions differ as to the ill effects of this chewing on them. On Europeans who became accustomed to, but had not been addicted to, its use from youth, Dr. Weddell noticed that it did sometimes produce evil consequences, and that in some a peculiar aberration of the intellectual faculties occurred, indicated by hallucinations. His view of its action was that it deceived or lulled hunger and fatigue. The Indians who accompanied him on his journey chewed coca during the whole day, but at night they filled their stomachs like fasting men. Dr. Mantegezza of Milan, who practised in South America, further tried and wrote on its marvellous properties, as did Sir Robert Christison. Mr. G. Dowdeswell also tried it, but came to negative conclusions as to its action. Except by the force of advertisements of French specialties made from it, coca has of late received little attention in England; but now, again, the observations of Herr Koller on the local anæsthetic action possessed by its alkaloid, cocaine, have brought it to the front.

Cocaine was, as we have stated, first isolated by Niemann in 1860; he obtained it by exhausting the drug with alcohol aciduiated with sulphuric acid, neutralising this liquid with lime, and filtering; the filtrate was again acidified with sulphuric acid, and the alcohol evaporated off. A semi-liquid greyish mass was obtained, containing the cocaine as a sulphate; from this solution it was precipitated with carbonate of soda, and purified by crystallisation from ether and alcohol. It is in shining monoclinic prisms, has a bitterish taste and a benumbing effect on the tongue. It requires 704 parts of water to dissolve it, it is more soluble in alcohol, freely so in chloroform, ether, and oil of cloves, and 1 in 20 respectively of melted vaseline and castor oil. The last two solutions have proved serviceable in eye cases. Manufacturers inform us that coca leaves yield only from 0·02 to 0·2 per cent. of cocaine. The leaves also contain hygrin (a volatile principle having the odour of trimethylamine) with ecgonine, coca-tannin, and coca-wax. Ecgonine (together with benzoic acid and methyl-alcohol) may also be obtained as a derivative from cocaine when the latter is heated with strong hydrochloric acid. Of its salts, the hydrochlorate has been most used; it occurs in small slender white crystalline needles, but in commerce looks like an amorphous powder. It usually has a peculiar odour, more marked than the alkaloid itself, probably due to a trace of hygrin as an impurity. Its action on the tongue and mucous surfaces is more intense than the alkaloid itself. It is soluble in one in four of water, and freely soluble in spirit. It is an antiseptic—a 5 per cent. aqueous solution delays the putrefactive changes in an extract of meat. The citrate of cocaine is in deliquescent small white crystals, and has been recommended for the use of dentists. Salicylate of cocaine, in minute snow-white crystals, has been preferred by some oculists, as it forms a solution which keeps well. An extract of coca, said to be an active preparation, is imported from South America, and a fluid extract, pastils, and wines of coca are also sold b chemists.

Before the discovery of cocaine, it was thought the alkaloid contained in it would probably prove to be identical with caffeine, or at least, like theobromine, allied to this. But chemically cocaine is quite distinct; it is much less soluble in water than caffeine; it is a strong base, which caffeine is not, and its chemical constitution and derivatives are quite distinct.

TREATMENT OF INTESTINAL OBSTRUCTION.

A DISCUSSION AT THE

LIVERPOOL MEDICAL INSTITUTION.

Dr. GEE, President, in the chair.

(*Continued from p. 1020.*)

DR. GLYNN considered that it was hardly necessary to discuss the medical treatment of intestinal obstruction; the general principles for the treatment of such cases had long been laid down, and every student even ought to be familiar with them. He necessarily thoroughly concurred with the remarks made on the inappropriateness of the administration of purgatives and enemata, on the importance of the withdrawal of almost all food, and on the value of opium. He doubted, however, whether the beneficial effects of opiates in cases of obstruction were due to their checking peristalsis. They undoubtedly lessened the vermicular movements of the intestines, but he did not believe that they could be prevented. When a dose of opium in health caused constipation, could it be supposed that it did so by virtue of its hindering the peristaltic action of the bowels, digestion being continued all the while? Moreover, in cases of obstruction of long-standing, where the intestinal walls were hypertrophied, the movements of the bowels, through the upheaving of the abdominal walls, could commonly be seen after large doses of opium or hypodermic injections of morphia. In acute cases, rumblings from the passage of flatus were frequently heard after the administration of sedatives, showing that the intestines were not at absolute rest. Dr. Glynn considered that opium should not be given with the idea of suspending the intestinal movements, as he believed that impossible. The entrance of the smallest amount of liquid food into the stomach would probably excite a flow of gastric juice, bile, and other fluids, and peristalsis be initiated. He considered opium should only be administered to relieve pain or check vomiting if excessive. With regard to operation for the relief of obstruction, he was of opinion that it could rarely be resorted to owing to the difficulty of making a diagnosis, and he thought surgical interference as a method of exploration hardly justifiable. He might illustrate the difficulties which attended making a correct diagnosis by referring to two cases which had been under his care in the Royal Infirmary. The first was that of a young man who had always enjoyed perfect health, and who was suddenly seized with pain in the right iliac region, followed by absolute constipation and incessant vomiting. On failure of the ordinary treatment to relieve the obstruction he was, at the end of three days, operated on by Mr. Reginald Harrison, when it was found that the trouble was caused by an inflammation in the neighbourhood of the cæcum, due to the eruption of a concretion from the vermiform appendix. In the second case the patient was an adult about fifty. He had been seized with sudden symptoms of obstruction without a history of any previous bowel trouble. The propriety of an operation was discussed, but no surgical interference resorted to, owing to the collapsed state of the sufferer. After death a cylindrical epithelioma of the cæcum was found, and the immediate cause of the urgent symptoms was the giving way of one of the several ulcers above the narrowed bowel.

MR. DAMER HARRISON thought it a significant fact that two or three of the previous speakers who had had a wide experience upon this subject had prefaced their remarks by stating that they had very little to say, and the debate so far had been remarkable for an entire absence of statistical information as to the results of treatment in acute cases. He had been looking through the post-mortem book of the Northern Hospital, and found that during the last four years there had been three acute cases. In the first case the obstruction was caused by a fibrous band, in the second by a loop of intestine being matted together, and in a third by the cæcum being displaced inwards beneath the free border of the mesentery. The last case was a very good illustration of the great difficulty which was met with in the diagnosis of these cases. It was that of a man who was admitted into the Northern Hospital under his care, with a history of having fallen from a height of five yards, alighting on his feet, and then again falling heavily upon his back. He complained of great pain across his back upon admission. His bowels were moved upon the two following days, but in the afternoon of the second day he began to vomit. He then gave a history of several attacks of vomiting during the previous six months, and in consequence of the history and surrounding circumstances attending the case the diagnosis was not made out until the fourth day, when the case had progressed beyond the point at which operative interference could be of any avail. With regard to treatment by laparotomy in acute cases, he could hardly agree with the statement of Mr. Thomas, "that providing a case was treated by the 'Sydenham' method it would remain in a condition favourable for operation until the third day," for he remembered two cases in which intestinal distension became troublesome in that time. Operative interference must be attempted, if at all, before any distension was present, and he therefore preferred not to accept any given time as the proper one to elapse before considering the advisability of

Digitized by Google

operation, and thought that each case should be judged of individually. With regard to how far operative treatment might be attempted in acute cases, he believed it was impossible to arrive at any conclusion until we had obtained a large amount of accurate information as to the results of treatment, and he would therefore not attempt to indicate under what circumstances abdominal section should be resorted to.

Dr. BARR highly approved of the papers read by Dr. Greves and Mr. Pughe, and was much pleased with the bold and successful line of treatment which they adopted in the very interesting case which they brought before the Society. Dr. Barr was of opinion that if surgeons were called in at an early stage of the case and operative interference more frequently practised, many valuable lives would be saved, and that the operation would not be attended by such a fearful mortality as follows it when merely used as a *dernier resort*; or like a drowning man catching a straw. He confined his remarks to cases of acute intestinal obstruction, the symptoms of which are well-marked in pronounced cases; but he thought that different practitioners attached different values to symptoms in any given case, and hence we find that the disease seems to be very common in some men's practice, while with others of equal, if not greater, experience it is comparatively rare. If you look upon all cases where you have got severe pain in the abdomen, constipation, and vomiting, with, perhaps, more or less shock, as cases of intestinal obstruction, then, no matter what line of palliative treatment you adopt, you ought to have a very good percentage of recoveries; but if you belong to a more exclusive school, and in your anxiety for accurate diagnosis, eliminate all cases of colic, constipation, enteralgia, &c, then you will find that you have a terrible disease left, which tends more frequently towards a fatal issue than to recovery. No doubt many very severe cases, under judicious treatment—rest, starvation, opium, hypodermic injections of morphia or combined with a small quantity of atropia (which prevents the sickness and depression which morphia often occasions when administered alone),—undergo spontaneous recovery; the bowel gets out of its knot or twist, or frees itself from its constricting band, or the impacted fæces soften, and the inflamed and paralysed portion of the bowel recovers its tone, or in cases of intussusception the invaginated portion sloughs away. But these are exceptional cases rather than the rule. Dr. Barr did not advocate indiscriminate operation, in fact he was strongly adverse to operation unless there were reasonable grounds to suppose that the patient could not otherwise recover. The physician should arrive at as accurate a diagnosis as possible; the surgeon should be called in early, and then if an operation were deemed necessary, there was no use delaying it until the bowels were all glued together by peritonitis, or the patient dying of septicæmia. He was puzzled to know why acute intestinal obstruction occurring within the abdominal cavity should receive different treatment from that which it receives when arising at some of the abdominal rings. Why should an internal abdominal hernia be treated by palliatives while an external receives powerful operative interference? In the latter case, if you fail to reduce the hernia you promptly cut down and divide any constricting band. Why not, then, in suitable cases of acute occlusion adopt a similar course, even though the operation be more grave? The cases are desperate, and justify a heroic remedy. Mr. Banks had spoken in a very guarded manner about operative interference, but Dr. Barr was pleased to think he was a more bold operator than his remarks would seem to imply, as last winter Dr. Barr sent a case of strangulated hernia into the Royal Infirmary, under the care of Mr. Banks, who in the operation cut away about twelve or fourteen inches of gangrenous bowel, stitched the edges of the two portions of sound intestine together, and the patient made a perfect recovery. Dr. Barr hoped that in future such excellent surgery would extend more deeply into the abdominal cavity.

Mr. RUSHTON PARKER considered the present discussion an advance on those of past years, and also thought that Dr. Greves and Mr. Pughe were to be congratulated upon their case, which they had so skilfully managed throughout. Their treatment was justified by the result, though he agreed that good luck as well as good management were on their side. The discrepant opinions that resulted from the study of restricted varieties of case, the differences in cause, and the similarity in symptoms, alike pointed to the difficulties of diagnosis for differential purposes. The recognition of symptoms of obstruction was easy enough, but why was the separate indication of their cause so difficult? No power had yet succeeded in making this generally possible, nor was it likely that any power ever would, owing to the very nature of the cases themselves. They might be classed under the following heads:—(1) The cases where symptoms of intestinal obstruction attended acute peritonitis, due to gradual escape of fæcal matter following perforation of intestine, frequently of the vermiform appendix. In these cases the patient died of septic poisoning, though the symptoms were those of obstructed intestine. Treatment was hopeless from the first, but we did not know that until afterwards, because the obstruction symptoms were similar to those arising from other causes, and might even be palliated by appropriate treatment; but in vain, for all these symptoms were subsequently overshadowed by the fatal virulence of the poisonous absorption. (2) The cases of pure functional obstruction, a numerous class, the symptoms of which were found, as in other classes, presenting every degree of acuteness or chronicity, severity or mildness, but which under the palliative treatment that we now all profess to approve were capable of recovery in a majority of instances. (3) An intermediate class of cases of internal strangulation, including intussusception, volvulus, band, and the like, not necessarily fatal, yet largely so, though a small minority recover spontaneously, under varying and even conflicting treatment, or after abdominal section. Among these cases there were no certain methods of distinguishing the varieties at first, and under operative treatment the successes were not more numerous than without. Even to open the abdomen was to run the risk of meeting with one out of the class just referred to, and operating both unnecessarily and harmfully. The careful adoption of expectant and palliative treatment would here enable us to save cases in which recovery was occasionally possible without sacrificing some in which that result would otherwise be attained with facility. He agreed with Mr. Davidson that there was no comparison between abdominal section undertaken for ovarian or other tumours and that practised for intestinal occlusion. While the advances in operative method, dressing, and after-treatment were shared by both sets of cases, the patients in obstruction cases did not seem equally capable of recovery, whether that were due to the previous state of the bowels or to some other cause. In the first class of cases to which he had referred all treatment was futile, in the third a small minority might be assisted by palliative treatment to undergo spontaneous recovery, but the second consisted of cases of which a majority were capable of easy recovery if not improperly treated, and often if let alone. Upon these his hopes were based, and it was in the interest of these that he recommended the assiduous adoption of palliative measures uniformly in all cases, after the plan laid down by Sydenham and fully elaborated by Mr. Thomas.

(To be concluded.)

THE BRIGHTON WATER-SUPPLY.

ON the 6th inst. a representative body of the water interest visited the waterworks at Brighton, the extension of the works being now completed after engaging the attention of the Town Council for some time past. Previously to 1853 Brighton obtained its water-supply from a well sunk in the chalk and from private wells in the town. In that year, however, Mr. James Easton advised the sinking of other wells and the cutting of tunnels at right angles to the fissures in the chalk, by means of which the surplus water had made its way to the sea, so as to intercept the water and carry it to the pumping station. This was done, and the tunnels were extended from time to time as more water was needed. From this source the whole town was supplied until 1865, when, owing to the rapid increase of population, a greater demand for water arose, and it was determined to construct another pumping station. A well was accordingly sunk to the west of the town, where a naturally formed basin occurs, and tunnels were driven to the extent of about a quarter of a mile across the valley parallel to the sea and intersecting the fissures in the chalk. From these sources a copious and constant supply of the purest water is obtained. It is found that the fluctuations are very slight, the difference of quantity of water being felt rather by the impossibility of the pumps lowering its level than in its rising higher. The area of the district supplied is considerable, being about

Digitized by Google

seven miles in length by five miles in breadth, the ground surface being of an undulating character. It has therefore been divided into four zones or services, each fed by its own reservoir with its own system of main pipes. Each reservoir is placed at a proper level relatively to the zone it supplies, so that, while a high pressure is given, over-pressure is avoided. The various services, however, form, together with the pumping stations, one complete system, each being only disconnected from the rest by valves and stopcocks. The reservoirs are covered, and the water is in no way exposed to any contaminating influence before it runs from the taps.

Up to within a few months ago the length of the main tunnel was about 2000 ft., but it has now been lengthened some 600 ft. more, besides being deepened, thus giving more than half a mile of intercepting galleries; these additions have been effected in eighteen weeks. The total available daily supply of water is now five and a half million gallons, but of this two million gallons are daily pumped into the sea, the present demand only reaching three and a half million gallons. Considering that the company have power to widely extend their workings if necessary, it would seem that, increase as it may, Brighton can never fail in its water-supply.

THE PROGRESS OF CHOLERA.

CHOLERA cannot yet be regarded as extinct in Paris; indeed, the latest weekly record which was published on the 4th inst. is to the effect that seventy-four deaths from that disease had occurred in the city during the preceding week. The announcement is, however, accompanied by an assurance that the prevalence is really dying out. From Spain come continual reminders that although the disease fails to assume an active form, yet it still lingers in that country. Four deaths have recently occurred at Vergel in the province of Alicante, and two more are reported from Toledo. A recrudescence of cholera is also announced from Italy, fifteen cases being reported as having occurred in the province of Salerno to the south of Naples; and the rumour appears to have some grounds, since, concurrently with it, we learn of the postponement of the abolition of quarantine measures in Sardinia and Sicily.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Diphtheria at Godmanchester, by Dr. PARSONS.—Godmanchester was inspected by Dr. Parsons in 1880; the cottages were found to be old, dilapidated and overcrowded; the sewers were of defective construction; the water was from wells liable to pollution, and some houses had none at all; offensive midden and cesspit privies prevailed; and there was much nuisance from filth and lack of scavenging. After a lapse of three years the only improvement that has been effected is that the worst houses are no longer inhabited, and that others have been supplied with eavespouts. But the first improvement is not apparently due to the sanitary authority; it has been brought about by a decline of population. In such a district, low-lying, damp, liable to floods, and all but absolutely neglected from a sanitary point of view, diphtheria finds a foothold. The population is just over two thousand, and there were six diphtheria and two croup deaths in 1883. The recommendations urged in 1880 are again repeated in 1884, and an analysis is appended showing that the water from a well which was deemed to be least of all liable to pollution, and which the Town Councillors pronounced to be very good as the result of a draught which they took at one of their sittings, contained so much chloride and ammonia as strongly to indicate sewage contamination. On the whole we think that Godmanchester would not lose by being merged into the rural sanitary district, instead of having independent sanitary existence.

Diphtheria at Huntingdon, by Dr. PARSONS.—Huntingdon, like Godmanchester, was visited by Dr. Parsons in 1880, and as a consequence some action was taken. New sewers, shafts were constructed for ventilation purposes, house-drains were disconnected, and pan-closets have replaced some old and offensive midden-privies. But some of the latter still remain in unwholesome proximity to houses and wells, and the arrangements for the removal of house refuse are unsatisfactory. There has been an extension of the town water in the place of local wells, and the old pest-house has been adapted to certain isolation purposes. Two deaths occurred from diphtheria in 1883, but not much information could, at the date of the inquiry, be elicited as to them. Some of the houses in which they were situated were in confined situations shut in by other buildings; some were in close proximity to offensive privies, and others had such means of drainage as to admit of their pollution by drain air. On the whole Huntingdon had made some substantial sanitary progress since the first inspection, but a further extension of the town water to houses still resorting to wells, the substitution of cleanly closets for the filthy privies that remain, and a better system of scavenging, are measures still needing to be carried out.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bethnal Green.—This important parish, with an estimated population of 128,370, had in 1883 a death-rate of 23·9 per 1000, the birth-rate being 33·9, and the death-rate under one year 162 per 1000 births. Scarlet fever was the most fatal infectious disease, and it caused 174 deaths. From the account given it is evident that good work is proceeding under the recent statute as to bakehouses. Unfortunately, as regards bakehouses occupied before June 1st, 1883, closets communicating directly with the bakehouse cannot be dealt with apart from their having produced nuisance, but an inspection of 137 such places is already leading to substantial improvement in Bethnal Green. The bread bakeries are not the worst; it is in the hidden recesses of the pastrycooks' and eating-house premises that the most objectionable conditions have been discovered. The cow-sheds are also carefully looked after, and, speaking generally, they are now in fair condition. With regard to the housing of the people, Dr. Bate urges the demolition of certain courts and alleys, for, many of them being built on the vicious back-to-back system, it is impossible to secure for them adequate ventilation. He also advises automatic trough closets for such localities. The report contains a special and full account of the comparative efficiency of certain disinfecting apparatus, and it concludes by advocating Lyon's high pressure steam machine. All interested in this subject would do well to read what Dr. Bate says on this point.

Hastings (Urban). — It appears from the quarterly return of the medical officer of health for this urban sanitary district (Mr. C. Knox Shaw) relating to the three months ending September last (only just to hand) that the birth-rate was 23·7, and below the average for the corresponding quarter in recent years; while the death-rate was 17·7, and exceeded the same average. It is stated that nearly 17 per cent. of the deaths in the borough during the quarter "occurred amongst non-residents or visitors"; and it is further noted that under the heading "deaths of visitors" are returned all deaths of persons who may be "temporarily sojourning in the borough." It would be well if further and more definite explanation of the term "visitor" were added in future returns, as "temporarily sojourning" is susceptible of somewhat wide interpretation. The return before us has two very unsatisfactory features, although the gross death-rate is comparatively low. Infant mortality, measured by the deaths of infants under one year of age to births, was equal to 19·9 per cent., which is exceedingly high for such a population as that of Hastings. This excess is, to a considerable extent, due to the other fact that the zymotic death-rate for the quarter was equal to 4·97 per 1000 of the population. The deaths referred to the principal zymotic diseases included 14 from measles, 14 from whooping-cough, 2 from diphtheria, and 28 from diarrhœa. Watering-places are exceptionally liable to infection from these zymotic diseases, but a high rate of mortality from such diseases cannot, even among watering-place populations, be disregarded as evidence of unsatisfactory sanitary condition.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5370 births and 4102 deaths were registered during the week ending the 6th inst. The annual death-rate in these towns, which had been equal to 20·9 and 23·8 per 1000 in the preceding two weeks, further rose to 24·4 last week. During the first ten weeks of the current quarter the death-rate in these towns averaged 21·4 per 1000, against 21·9 and 21·1 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 18·4 in Portsmouth, 21·3 in Wolverhampton, 21·7 in Leeds, and 21·8 in Bristol. The rates in the other towns ranged upwards to 30·2 in Blackburn, 30·9 in Sunderland, 32·5 in Preston, 22·7 in Halifax, and 38·7 in Oldham. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 391 and 396 in the previous two weeks, were 391 last week, and included 80 from measles, 76 from scarlet fever, 69 from whooping-cough, 52 from "fever" (principally enteric), 42 from diphtheria, 37 from small-pox, and 35 from diarrhœa. These zymotic diseases caused the lowest death-rates last week in Wolverhampton and Nottingham, and the highest in Derby and Cardiff. The greatest mortality from measles was recorded last week in Bolton and Cardiff; from scarlet fever in Sunderland and Brighton; whooping-cough in Oldham and Leeds; and "fever" in Salford, Birkenhead, and Plymouth. Of the 42 deaths from diphtheria in the twenty-eight towns, 29 occurred in London, 3 in Liverpool, and 2 in Nottingham. Small-pox caused 52 deaths in London and its outer ring of suburban districts, while no death from this disease was recorded in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had increased from 580 to 884 in the preceding four weeks, had further risen to 1027 on Saturday last; 263 cases were admitted during last week, against 149 and 228 in the previous two weeks. The Highgate Small-pox Hospital contained 80 patients on Saturday last, 35 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 354 and 511 in the preceding two weeks, declined to 499 last week, and were 11 below the corrected average. The causes of 102, or 2·5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Salford, Bradford, Plymouth, Derby, and Cardiff. The largest proportions of uncertified deaths were registered in Oldham, Hull, and Wolverhampton.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 22·3, 26·2, and 28·6 per 1000 in the preceding three weeks, further rose to 31·8 in the week ending the 6th inst., and exceeded by no less than 7·4 the mean rate during the same period in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 22·1 and 25·2 in Edinburgh and Perth, to 35·3 in Dundee and 37·3 in Glasgow. The 768 deaths in the eight towns included 42 which were referred to whooping-cough, 34 to measles, 25 to diphtheria, 14 to diarrhœa, 13 to scarlet fever, 12 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 140 deaths resulted from these principal zymotic diseases, against 115 and 101 in the preceding two weeks. These 140 deaths were equal to an annual rate of 5·8 per 1000, which was no less than 3·5 above the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 27 and 19 in the previous two weeks, rose to 42 last week, and included 15 in Glasgow, 6 in Dundee, 5 in Edinburgh, and 5 in Leith. Of the 34 deaths from measles, 17 occurred in Glasgow, 12 in Aberdeen, and 5 in Dundee. The 25 deaths attributed to diphtheria included 8 in Glasgow, 6 in Dundee, 4 in Edinburgh, and 3 in Paisley. The 14 deaths from diarrhœa corresponded with the number in the previous week; while the 13 from scarlet fever (of which 11 occurred in Glasgow) showed a further decline from recent weekly numbers. Of the 12 deaths referred to "fever" (principally enteric), 4 occurred in Glasgow, 2 in Edinburgh, and 2 in Leith. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 101, 145, and 181 in the preceding three weeks, further rose to 231 last week, and were more than double the number (115) returned in the corresponding week of last year. The causes of 116, or more than 15 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had steadily increased from 24·7 to 35·4 per 1000 in the preceding five weeks, declined to 33·2 in the week ending the 6th inst. During the first ten weeks of the current quarter the death-rate in the city averaged 29·3 per 1000; the rate during the same period being only 19·7 in London and 19·8 in Edinburgh. The 228 deaths in Dublin last week showed a decline of 15 from the high number in the previous week, and included 25 which were referred to the principal zymotic diseases, against 39 and 23 in the previous two weeks; 9 resulted from scarlet fever, 4 from measles, 4 from whooping-cough, 3 from "fever," 3 from diarrhœa, 2 from diphtheria, and not one from small-pox. These 23 deaths were equal to an annual rate of 3·7 per 1000, the rate from the same diseases being 2·3 in London and 3·4 in Edinburgh. The deaths from scarlet fever in Dublin, which had been 16 and 11 in the previous two weeks, further declined to 9. The fatal cases of measles, which had been but 1 in each of the previous four weeks, rose to 4 last week. The numbers from the other zymotic diseases did not materially differ from those in the previous week. Six inquest cases and 2 deaths from violence were registered; and the 60 deaths in public institutions showed a decline from the numbers in the previous two weeks. The 69 deaths of elderly persons exceeded the number returned in any previous week of this year. The causes of 42, or 19 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—The Queen has been pleased to issue a new Commission of Lieutenancy for the City of London, constituting and appointing, amongst others, the undermentioned to be Her Majesty's Lieutenants within the said City—viz., William Sedgwick Saunders, Esq., M.D.; Thomas Boor Crosby, M.D.

ARMY MEDICAL STAFF.—Surgeon-General Richard Gilborne has been placed upon retired pay; Deputy Surgeon-General Adam Graham Young is granted retired pay, with the honorary rank of Surgeon-General; Surgeons-Major William Jobson, M.D., Richard Turner, M.D., and John Murray, M.B., are granted retired pay, with the honorary rank of Brigade Surgeon.

INDIA OFFICE.—The Queen has approved of the retirement from the Service of Surgeon-Major William Edward Allan, of the Bengal Army.

The undermentioned Officers are granted a step of honorary rank on retirement:—Brigade Surgeon George Vernon Currie, of the Bengal Army, to be Deputy Surgeon-General; Surgeon-Major Henry William Graham, of the Bengal Army, to be Brigade Surgeon.

ADMIRALTY.—The following appointment has been made: Frederick A. Saunders to be Surgeon and Agent at Crail and Fifeness.

SANITARY ASSURANCE ASSOCIATION.—Professor F. De Chaumont, F.R.S., presided at the third lecture on Sanitary Assurance at the Parkes Museum on the 10th inst. when Dr. Beatson lectured on "Sanitary Assurance at a Health Resort," with special reference to Bath. He said the grisly phantom of cholera had cast its shadow this year over some of the fairest places in Europe; places beautiful without, but from want of sanitation, full of uncleanness within. We were told that it would find no foothold in our island. He hoped it might be so, but were there not insanitary houses in every town and city with doors open ready to receive it? In the discussion which followed, Sir Joseph Fayrer, F.R.S., Mr. F. B. Jessett, F.R.C.S., Surgeon-General Ringer and Mr. Melton Gibbs, architect, took part. The lecturer next Wednesday will be Mr. Mark H. Judge, A.R.I.B.A., and his subject "Public and Private Responsibility in Sanitary Matters."

DR. LOWSON'S CASE.

To the Editor of THE LANCET.

SIR,—The remarkable case of diabetes following diphtheria, which I now enclose to you, is related by the sufferer himself, Dr. Lowson, of Hull, then of Huddersfield. As Dr. Lowson received the Albert Medal for his heroism in dealing with the diphtheria in the first instance, I think I need not publish the case anonymously. Diabetes being not unknown as a sequel of diphtheria, I had little hesitation at the outset in giving Dr. Lowson a favourable prognosis.

Yours faithfully,

Dec. 7th, 1884. T. CLIFFORD ALLBUTT.

"Wycliffe House, Anlaby-road, Aug. 26th, 1884.

"DEAR DR. ALLBUTT,—The following is, I believe, an accurate description of my case:—On the 12th of November, 1679, sent for in haste, I went to see a child six or seven years of age, living about 300 yards from the surgery. Having suffered three or four days without professional assistance, I found her in a very critical state. Inspiratory laryngeal dyspnœa, with exaggerated inspiratory effort, cyanosis of the lips and face, and unconsciousness, showed me that she could not live long without help. I fetched with all speed the ordinary tracheotomy case, and opened the windpipe in the usual manner below the isthmus. Respiration did not improve sufficiently to remove the cyanosis; and as I had no pipette with me, and the danger being imminent, my only resource was to suck the wound. I need scarcely say that I gargled and washed out my mouth well at the time with water, and later on with carbolic acid solution. The child improved for a time, but died on the fourth day with diphtheritis of the wound and extensive and hard filtration for a considerable distance around. On examining the throat of the child after the operation, no false membrane was to be seen anywhere; but after a forcible expectorant effort I found that a piece had been expelled through the tracheotomy tube, and had adhered to the front of my coat. It somewhat resembled colourless fibrin clot, but was hardly so friable. On the evening of the 16th, notwithstanding my disinfectant gargling, I found myself with high fever, and, thinking I had caught cold, I took a lamp-bath and went to bed about 11 P.M. My temperature was 102°. Sore-throat followed, and soon a membranous patch made its appearance on the left tonsil. This spread along the margin of the palate, including the uvula. A smaller patch appeared on the other tonsil, and a narrow strip along the margin of the epiglottis. Separation easily occurred, and no renewed deposition took place. One night a piece hanging from the uvula, and tickling the top of the larynx, kept me a long time awake till it was expelled by retching. The throat was very sore and raw, and deglutition painful for several days after. Nothing remarkable occurred in convalescence till about the end of December, when, on testing my urine for albumen, it struck me I might as well look for sugar, and to my surprise a strong reaction resulted. I had used the ordinary sulphate of copper test, and freshly prepared Fehling gave the same result. The quantity of urine did not rise much above normal, except during the first fortnight after the discovery of the sugar. There was no diabetic thirst, and the appetite remained poor. Morphia was now taken in small doses, and a decrease in the strength of the reaction gradually took place. The whole of January my health was bad, and the spirits were depressed or apathetic. About the beginning of February I noticed a difficulty in swallowing. I had to make two or three grasps at the morsel before I could push it from the pharynx into the more lively œsophagus, and I became afraid of liquids, and had to drink slowly and with sudden gulps made with an effort. This paretic symptom did not become marked or severe, and it was, I believe, considerably aggravated by nervousness, for I gradually seemed to gain confidence, and then it disappeared; about this time the glycosuria also became intermittent. I was pleased one day to find no reaction at all. I now became careless with the sodipine, either omitting it purposely or forgetting to take it. Finding, however, that this was followed by restless, fidgety, and sleepless nights, with return of the golden precipitate, I became again more regular with my dose. The last appearance of the complaint was about the middle of April, probably due to two days' omission of the morphia mixture. In May I embarked on a two months' voyage up the Mediterranean. This worked wonders. My health improved daily at sea, and though tested many times since then, no more sugar has been detected in the urine. I have therefore been now four years free from all trace of the disease. With regard to diet, I was strict only for a fortnight. Eating gluten bread is not my *forte*, and fortunately the sugar did not increase on returning to my normal food. Besides being tested by myself, my urine was also examined by Dr. Churton at your request, when the reaction was slight, but sufficiently marked; and by Dr. Coutts (Waterfoot, Lancashire), who found a large quantity of sugar present.

"I am sorry now that I did not follow the symptoms with greater care, and that I did not make any volumetric analysis. I see that Oertel (in 'Ziemssen') mentions congestion and small hæmorrhages in the brain and cord, as well as softening around these points; also the development of lymphoid nuclei and cells and increase of areolar tissue, to the primary compressing influence of which he attributes the paralyses. As the centre of deglutition lies in the floor of the fourth ventricle, the part influenced by the diabetic puncture cannot be far off (vagus centre). May not the same cause to which the diabetes was due have also slightly affected the deglutition centre by continuity? I am afraid my case will not satisfy you, but if you wish to ask anything more I shall do my best to answer you, and if the pruning knife is required, I hope you will use it as required.

"D. LOWSON."

COCAINE.

To the Editor of THE LANCET.

SIR,—As it is only by recording clinical facts in regard to this new agent that we can arrive at just conclusions as to its value, I trust you may be able to afford me space for a brief *résumé* of some of the cases in which I have used it.

CASE 1.—W. S——, aged thirty-three, from Sleaford. This patient came under my notice in July suffering from a wound of the cornea and cataract caused by the impact of a piece of steel; no foreign body was to be seen, and his medical attendant concluded that the metal had rebounded. By means of a strong magnet, however, I discovered and extracted a large piece of steel, and subsequently removed the cataract. Last week he applied to me to be treated for closed pupil, which followed the last operation. I proposed to make an artificial pupil, operating as before without either ether or chloroform; but the patient, who on former occasions had exhibited great fortitude, appeared now to have completely lost his nerve and would not submit without an anæsthetic. I applied cocaine, assuring him that he would not suffer; he, however, insisted on an anæsthetic, and my colleague, Mr. Worth, therefore proceeded to administer ether. After a few inhalations he became alarmed, struggled violently, declared we were killing him, and refused to take more. I said, "You have had quite enough, you must feel it now," and proceeded to operate, fixing the eyeball and excising a portion of iris without the least manifestation of pain on the part of the patient. On interrogating him subsequently he declared that in comparison with former operations the sensation on this occasion was absolutely [illegible].

CASE 2.—Mrs. B——, aged seventy-four, [illegible], near Leicester. Extraction for cataract in left eye. [illegible] per cent. solution of cocaine was dropped into the eye three times at intervals of five minutes. The operation, including a slight iridectomy, was completed without [illegible] and the patient declared she suffered but very little pain.

CASE 3.—Ann C——, aged seventy, from [illegible]. Extraction for cataract in right eye. Operation successful, with but slight evidence of pain.

CASE 4.—David C——, aged sixty-five, from [illegible]. Extraction for cataract in right eye. Operation successful; he said he felt very little pain.

CASE 5.—William W——, from [illegible]. Double extraction for cataract in right eye, [illegible] instilled as in the first and other cases [illegible]. The patient bore the operations remarkably well [illegible], but said the operation on the left [illegible].

CASE 6.—W. U——, aged eighty-three, [illegible].

Digitized by Google

This patient was quite blind in the right eye from retinal disease, and in the left from cataract. I extracted on the left eye as in former cases, using cocaine. The patient was absolutely immobile, and declared that he felt no pain.

CASE 7.—C. L——, aged seventy-two, from Alfreton. Iridectomy preliminary to extraction for cataract; cocaine instilled as in former cases. In this case the patient was very unruly, and complained quite as much as though no cocaine had been used.

CASE 8.—Anne R——, aged fifty, from Retford Union. Iridectomy for glaucoma in the left eye; right eye lost from the same disease six years ago. Cocaine was instilled as in former cases, but the patient complained so much of the speculum and attempts to fix the eyeball that it was necessary to administer ether before excising a portion of the iris.

CASE 9.—Sam. M——, aged seventy, from Old Bursley. Extraction for cataract in the right eye. Operation completed without misadventure. Patient said he "felt very little pain."

The above cases, which I have treated within the last three weeks, together with numerous other minor operations, such as the operation for squint, removal of tumours, probing the lacrymal duct, &c., appear to me to afford conclusive evidence of the value of cocaine as a local anæsthetic. It causes dilatation of the pupil, which I obviate when desirable by using eserine at the same time. This dilatation is, however, unlike that occasioned by atropine and other mydriatics, unaccompanied by impaired accommodation, and it will therefore take the place of atropine in cases where such dilatation is desired merely to enable us to examine the fundus of the eyeball. It will probably be also much safer to use in cases where there is any threatening of glaucoma. Cocaine acts splendidly in cases of strumous ophthalmia accompanied by great intolerance of light, and is a useful adjunct to other treatment in all painful affections of the eyeball.—I am, Sir, your obedient servant,

CHARLES BELL TAYLOR, M.D., F.R.C.S. Edin.,
Dec. 1884. Surgeon to the Nottingham and Midland Eye Infirmary.

To the Editor of THE LANCET.

SIR,—My experience of the value of cocaine as a local anæsthetic for ophthalmic operations corresponds with that of Mr. H. Power and other writers in THE LANCET.

In the early part of October the drug was procured for my use at the Sheffield Infirmary, but in consequence of the "faint praise" accorded to its efficacy at the meeting of the Ophthalmological Society on October 9th, it was just then but little employed. During the last fortnight it has been extensively tested, and the accompanying list of operations have been performed with its aid during that period, and it will be seen that they embrace a large variety. Among the largest number of cases a 2 per cent. or 4 per cent. solution has been employed; in two instances a 20 per cent. was used.

Extraction of cataract was performed on two men, aged fifty and over seventy; in another man, aged fifty-seven, opaque capsule was needled. In the first two instances no speculum was employed; in the latter, both speculum and forceps were used. A little boy, aged two, also had opaque capsule (after congenital cataract) needled. The first three operations were quite painless; no iris was removed in the extraction cases. In the case of the child, as far as could be judged, the effect was equally satisfactory.

An iridectomy for closed pupil was performed on a man, aged sixty-seven; no pain until the excision of iris.

A woman, aged about forty-five, was operated on for conical cornea, by removal of a small flap from the apex. She had several months previously had the other eye similarly and successfully treated without chloroform. The cornea, after instilling the cocaine solution twice before the operation in about eight minutes, was quite insensitive, and the operation was completed without pain to the patient.

A little boy, with sloughing ulcer of cornea; pain was relieved after dropping the cocaine solution into the eye, and the ulcer was cauterised with platinum cautery, without suffering.

Two cases of squint, one in a boy aged eleven, and the other in a girl aged eight, have been done. The former was operated upon in one eye one week and the other eye in the next week. The suffering was nil until the division of the tendon, and was altogether so slight that he at once after the first operation consented to a second if necessary. The girl asserted she had felt very little pain.

Tarsal cysts have been operated upon in three instances. The primary incision has appeared to cause less pain, but the introduction of the curette into the interior has occasioned the usual discomfort. A man, with hypopyon ulcer of cornea, for which keratotomy was performed, derived comfort from the use of cocaine. On the day this is written a man with pterygium has undergone operation for its cure. During the eight or ten minutes preceding the operation a 4 per cent. solution of cocaine was instilled twice, and at the time of operating the cornea and conjunctiva had become quite insensitive. A speculum was inserted, the conjunctiva seized by forceps, the pterygium separated from the cornea, and, lastly, a suture was inserted, and at the end the patient declared he had felt nothing. It should be added that during the progress of the operation the cocaine was again dropped into the eye.

Foreign bodies have been removed from the cornea in five instances; two were from lads aged thirteen and fourteen. Of the latter, a boy aged fourteen, it is stated that in four minutes after using the 4 per cent. solution the foreign body was removed without pain. In ten minutes sensation was returning. No dilatation of the pupil was observed during the time. A 20 per cent. solution was employed in one of these cases of foreign bodies in the cornea. The patient was a man aged forty-five; anæsthesia came on immediately, and in one minute after the cocaine solution was instilled the piece of metal was removed without pain. The cornea and conjunctiva remained insensitive, but in twenty minutes sensation had returned and the pupil was dilated.

This strong solution was used also in one of the cases of tarsal cysts. It appears that the strong solution acts more rapidly, and that the effects last longer than the weaker, but perhaps generally speaking a 4 per cent. solution is sufficiently powerful.

The effects on the pupil have not been so carefully noted, but I should be disposed to regard its action in this way as uncertain. In a man for whom for ophthalmoscopic purposes the drug was instilled, 4 per cent., at the end of twenty minutes there was no appreciable effect on the pupil. It remains to be seen how atropine will act in his case. In other instances, also, when the cocaine has been used for its anæsthetic effects mydriasis has not been noted; but, of course, our observations in these cases may not have been sufficiently prolonged. On the other hand, in the conical cornea, and the man for whom the needling was performed, the pupil had dilated decidedly after the lapse of the few minutes from the time of instilling the solution to that of the operation. In the girl with squint, also, at the end of eight minutes mydriasis was decidedly marked.

It should not be omitted that in a woman with extensive burn involving the lower eyelid and ocular conjunctiva the instillate of the cocaine always gave her comfort, and, when it was necessary to tear through any adhesion, lessened the pain of doing it.

In aural surgery, I believe, the drug will be of service. A few days since I pressed on to a small polypus a portion of cotton-wool soaked with a 2 per cent. solution, and on touching it afterwards sensation was distinctly deadened. It may be of use in some cases of earache, and may render aid in posterior rhinoscopy.

The effect of cocaine on the skin, as others have stated, appears to be *nil*. I have placed on the front part of my forearm a piece of lint soaked with a 20 per cent. solution of cocaine, and covered it with gutta-percha tissue. After eighteen minutes the skin was still as sensitive as the surrounding parts.

My experience has satisfied me that the drug has a real value, and that an extensive use lies before it in surgery. I am indebted to Mr. J. R. Turner for the records of my cases.

I am, Sir, yours faithfully,

SIMEON SNELL,
Ophthalmic Surgeon to the Sheffield General
Dec. 1884. Infirmary.

SCOTCH MEDICAL EDUCATION AND EXAMINATIONS.

To the Editor of THE LANCET.

SIR,—As considerable misrepresentation has latterly appeared in the London medical papers with reference to Scotch medical education and degrees that has been altogether unfair and illogical, I venture under the circumstances to

Digitized by Google

submit to your consideration the following facts. In surveying the history of British medical education for the last 100 years, it will be plainly evident that the Scotch have been decidedly in the van. The Scotch universities have not only insisted on an efficient curriculum, but have allowed none to take their degrees without undergoing a competent examination in the four essentials of medical practice—viz., medicine, surgery, midwifery, and medical jurisprudence. If we turn to England we find a different state of things prevailing there. The chief examining body—the Royal College of Surgeons—has been so considerate to the community as to allow those to qualify who had a knowledge of surgery alone, the qualification practically enabling them to undertake all the branches of the profession, with total ignorance, perhaps, of the principles of medicine and midwifery. It is only necessary to investigate the pages of the Medical Directory in order to verify this fact. It is only within the last few years that this august body have awakened from their lethargy to the due appreciation of their obligations to the public.

With regard to the relative severity of the examinations of the two countries, it will only be necessary to state the following:—Taking the University of Edinburgh as an index of the Scotch, and the Royal College of Surgeons as an index of the English, and submitting the two to the cold evidence of statistics, we find the following:—

EDINBURGH UNIVERSITY.

First Professional Examination	....	50 per cent. rejected.	
Second "	"	 50	" "
Final "	"	 40	" "

This shows that in the aggregate about 85 per cent. are remitted for their degree. The Royal College of Surgeons' Primary and Final Examination show, in their results, a percentage of failures of about 65 per cent.

Nearly every professor in the University of Edinburgh has been, or is, an examiner in the University of London—viz., Professors Turner and Cunningham, Anatomy; Professor Rutherford, Physiology; Professor Crum Brown, Chemistry; Professor Fraser, Materia Medica; and Professor Balfour, Botany—and they will severally tell you that the standard in the London University is no higher than that of Edinburgh.

In conclusion, I may state that the University of Edinburgh had a chair of Pathology fifty years before that of any other medical school in the United Kingdom, and that now it is the only examining body that sets a separate paper on Pathology. Apologising for trespassing on your valuable time,—I remain, Sir, yours faithfully,

E. K. CAMPBELL, M.B. Edin., M.R.C.S.

Nov. 22nd, 1884.

CASES OF SEVERE DIARRHŒA AT THE BOOTHAM LUNATIC ASYLUM.

To the Editor of THE LANCET.

SIR,—I beg to forward you the following notes, which you may consider sufficiently interesting to record.

On the morning of the 13th ult., very numerous cases of diarrhœa of a severe type were reported to me as having occurred during the previous night among patients and attendants. In the worst cases the diarrhœa was accompanied by severe colicky pains and cramp; several (females only) were sick as well as purged; a few had severe griping pains but no diarrhœa. In the majority of cases the diarrhœa commenced at nightfall and had ceased by 10 A.M. Those affected with griping pain were relieved on the evacuation of the bowels after a dose of castor oil. The after-effects were that some patients habitually constipated said they felt better than usual; in a few the diarrhœa continued and recurred at times for a week or more; several were somewhat enfeebled for a few days; the majority were not affected in their general health.

After careful inquiry into every article of food and drink, I came to the conclusion that the roast beef which had been the almost universal dinner at midday on the 12th ult. was the only substance which could have caused the attack. I found that 158 persons had beef, or beef gravy; of these 135 had severe diarrhœa, or diarrhœa and vomiting; nine had slight diarrhœa or griping pains; thirteen (including some doubtful cases where the patients were demented and unable to give information) were not affected. Ten persons had milk diet, or minced mutton; all these were unaffected. The gravy appears to have been especially harmful; for twenty-three persons had other meat but with the beef gravy, and all these, except one who took no gravy, were similarly affected. The same beef eaten cold without gravy was not injurious. The cook had thought the beef a little dark coloured, and that the gravy did not flow freely from it when cooked. Some uncooked joints which I saw seemed to be from a well-fed beast; the fat was a good colour; the lean somewhat red and not of a bluish tinge when fresh cut, but not sodden or unhealthy looking, nor of a bad odour; the meat of the cold joints was perhaps a little dry, but nothing unnatural in smell or taste. The beast from which the meat was taken was as usual bought in the market on the Thursday previous, taken to our own slaughter-house, and there killed and cut up.

I found that the beast was a well-fed, healthy ox, which had been brought up at a farm four miles from here, where it had always been kept in company with another beast; that on the morning of Thursday it was attempted to drive the beast to market without its stall companion; the animal resisted so much, and got so wild, that after the drover had got it half way he was obliged to turn it into a field by the roadside whilst he returned to the farm he had started from, and fetched the companion beast. He then drove the two beasts together to market, and they travelled well enough. The beast was bought in the market, and on its being driven to the Asylum Farm, to the slaughter-house there, it again became furious, and the drovers had difficulty in getting it into the yard, and when shut up it continued beating itself about, and was very excited. At the time it was slaughtered the butcher noticed that the blood did not flow from the carcass as freely as it should have done, but all the parts of the beast and its internal organs were perfectly healthy.

I remain, Sir, yours truly,

CHARLES KNIGHT HITCHCOCK.

The Lunatic Hospital, Bootham, York, Nov. 1884.

"OVER-PRESSURE IN EDUCATION."

To the Editor of THE LANCET.

SIR,—Your article of Nov. 15th, on the above subject, is crushing in its clearness and force, and it is a pity that the ay press do not quote more from your journal when matters of such momentous interest to the present and rising generation are being discussed in its columns. We all know that the authority of THE LANCET in matters medical is in the end supreme, and though it may suit some officials to ignore the voice of the medical press for a time, their capitulation is eventually certain.

There is one argument against "forcing" the brain by overwork, and often useless work, in early life, and I fancy a very strong one, which I should like to point out, and it is this: that according to all we know of that organ, it is the last to reach perfection of growth and maturity of any in the body, and therefore of all others the last that should be overworked in childhood, when its specific gravity and development are utterly incomplete and unfitted to bear overstraining. Whereas the body ceases to grow after the age of twenty-five years, the brain, we know absolutely, grows in bulk for fifteen years longer; and if the mind is any index of its perfections, it certainly increases in strength and capacity for sustained work for fifteen or twenty years after that. The functions of the brain may be as stunted and crippled as those of the body often are; they may be cramped, dull, introspective, or precocious; and accordingly they require intellectual work in proportion to their development. And more than this, the functions of the brain are as much dependent on the consumption of matter in the shape of food as are those of the body; therefore it is absurd to expect the half-starved child to do the same amount of work as the well-fed one may be put to do with impunity

It is a well-known axiom that early maturity, physical or intellectual, means early decay, and if the present mode of education, by doing this, deteriorates the brain and nervous system of the rising generation of children, how much worse will it be for the next one, the produce of an enervated and morally and physically enfeebled race. The days for whipping children to death in schools are gone—let us hope never to return again. We are more refined now; we whip their brains to death instead; and if the brutality is not so repulsive to the looker-on, or so palpable, it is equally efficacious in the end, and far more cruel, as the process is slower

Digitized by Google

and its ultimate consequences are more serious, for they affect generations yet unborn.

YOUR correspondent, Dr. R. Macpherson, in last week's LANCET, has given a graphic account of the evils of the present system of education, and I do not believe that there is a medical man practising in England who cannot recall cases illustrating this evil of over-pressure, especially among the children of the poor.—I am, Sir, yours, &c.,

Sherborne, Dec. 1st, 1884. NATHANIEL EDWARD DAVIES.

THE LONDON UNIVERSITY.

To the Editor of THE LANCET.

SIR,—Many hard things are being said just now about the University of London, some of them indeed just, but others very unjust. The most amusing suggestion, however, comes from Manchester, and is set forth under the heading "Victoria University," and is supplied by your correspondent there. He suggests that King's College and University College should take steps to become affiliated with the so-called "University of the North." Now, Sir, while the whole body of the profession is yearning for some "conjoint scheme" we are meanwhile saddled with a twentieth licensing body, and while it seems to be the fashion to grumble at the exclusiveness and so-called tyranny of the London University, nothing is said about the intolerance and illiberality of the newest of the universities. The gateway to the Victoria is if anything more strongly guarded than that of the London, and there is added, besides, that antiquated humbug of exclusiveness which is included under the offensive word "affiliation." The medical students of King's and University Colleges will be quite capable of taking care of themselves in the matter of examinations, which are not less stiff in the northern university than the proverbial ones held at Burlington House. In the name of justice and common sense how is it that the one university is perpetually abused while the new one is pursuing vigorously unheeded the same policy to a much greater degree.

I am, Sir, yours obediently,

WILLIAM DYSON, B.A., M.D. Lond.

Sheffield, Dec., 1884.

EXAMINATION OF ARMY MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—With reference to my letter in your issue of the 22nd ult., wherein I advocated the desirability of allowing surgeons-major to take the examination for promotion to the rank of brigade surgeon at an earlier period than after twenty years' service, I find that the revised War Office circular of Nov. 1st has omitted the words "after twenty years' service," thus leaving the time when a surgeon-major may be examined perfectly open in future. I should fancy every such officer who wishes to pass will be afforded the opportunity between his fifteenth and twentieth year of service. This is as it should be, and the new examination, by inviting officers of this standing to take stock of their experience and to correlate it with the latest advances in military medical science, will tend to make them very accomplished indeed in this their specialty. I have been afforded an inspection of the papers given at the recent examination, the first of its kind. The questions are, as I anticipated in my previous letter, eminently practical. Every officer of any experience should, I would say, be able to give satisfactory replies to most of them. The wisdom which comes from experience, not from books, has been asked to show itself, and I do not doubt that on this first occasion it has done so.—I am, Sir, yours &c.,

December, 1884. G.

LIVERPOOL.

(From our own Correspondent.)

THE RECENT CASE OF GOOD *v.* WHITTLE AND OTHERS.

THE hardships inflicted on medical practitioners in the regular and legitimate discharge of their duties are well illustrated in the recent case of Good *v.* Whittle and others. That the defendants believed themselves to be thoroughly justified in the course they took is beyond dispute. That they had good and sufficient grounds for their belief is clearly shown by the charge of the presiding judge (Justice Cave) and the verdict of the jury. And yet the defendants' costs amount to upwards of £630, of which they will have to pay £470, one-fourth (Dr. Mould's share) having been borne by the asylum authorities. The plaintiff, as is very frequently the case, being unable to pay, the costs fall upon the defendants. A fund is being raised (as noticed in the last issue of THE LANCET), and subscriptions have already come in. It may happen to any practitioner to be placed in the defendants' position, and it is greatly to be desired that the whole amount may be raised. Dr. Nevins is the treasurer, and subscriptions may be paid to him or to the Whittle and Hutchineon Fund, North and South Wales Bank, Hardman-street, Liverpool.

THE MAYOR AND THE ROYAL SOUTHERN HOSPITAL.

For upwards of forty years it has been the custom for the newly elected Mayor to attend the morning service in state at St. Barnabas Church on the second Sunday after his election, when a sermon is preached and a collection made on behalf of the Royal Southern Hospital. In accordance therewith the Mayor (Alderman David Radcliffe) attended on the 23rd ult., when a sermon was preached by the Bishop of Sierra Leone, and a collection made which amounted to £102. After service the Mayor, accompanied by Lord Claud Hamilton, M.P., and others, visited the hospital and went through some of the wards, accompanied by members of the medical staff.

HEALTH OF LIVERPOOL.

At the weekly meeting of the Health Committee on the 4th inst. the medical officer stated that there were fourteen cases of small-pox in the new hospital, also that twenty-three cases of scarlatina had been reported, which latter were not confined to any particular locality, but were spread all over the city. The death-rate was equal to 27·5 per 1000 of the estimated population.

THE LOCK HOSPITAL.

For some months past the wards of the Lock Hospital, both male and female, have been unusually full, and the number of beds being very limited the cases are mostly syphilitic, the exceptions being gonorrhœa with severe complications, or chancroids which, from neglect, dirt, and drink, have assumed a sloughing character. Of the latter there have been several instances lately, these cases always occurring in groups; the same remark applies to cases of orchitis and epididymitis, and the more severe forms of syphilis. Dr. Bernard has recently had in his ward several cases of glassblowers, all of whom had contracted constitutional syphilis by using the blowpipe of an infected fellow-workman. The cases commenced with chancres on the lips, accompanied with enlargement and induration of the submaxillary glands, and the subsequent appearance of roseola. The genital organs were entirely free from any appearance of disease, and there could be no doubt as to the source of infection. Dr. Bernard's clinical class has been well attended.

DEATHS FROM HOMICIDAL STRANGULATION.

At the recent assizes two cases of murder by strangulation were tried before Mr. Justice Day. One occurred in Manchester, the deceased being the wife of the prisoner. She was found dead by the neighbours, whom the prisoner called in, and with certain marks of violence on her neck, which were quite inconsistent with the prisoner's statement—viz., that "she had fallen into the fender while they had a bit of a bother." The body was seen first by Mr. Berkeley, assistant to Dr. Sutton, and the prisoner was taken in custody. Dr. Sutton made the post-mortem examination, and attributed the death to asphyxia from strangulation. Dr. Cullingworth, Professor of Medical Jurisprudence at Owens College, who also examined the body, gave as his supposition that death had been caused by pressure on each side of the neck, where bruises were visible just over the course of the internal jugular vein and carotid arteries. The cerebral veins were very much congested, so also were the lungs, but not so much so as in ordinary cases of strangulation, where the windpipe has been compressed. The prisoner was convicted and executed on Monday last, having previously fully confessed his guilt. In the other case, which arose out of a drunken Irish row at Upholland, near Wigan, Dr. J. L. Molyneux gave evidence. The appearances of strangulation were well marked. The prisoner was found guilty of manslaughter, and sentenced to twelve years' penal servitude.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

DR. ZUKERTORT, THE CHAMPION CHESS PLAYER.

DR. ZUKERTORT has been astonishing all chess-players in this neighbourhood (and our own *confrères* number a few of the best) by his fine play at the Art Gallery in this city last week. He played sixty games, winning fifty-one; he also played twelve of our best amateurs blindfold, winning or drawing all. Our phrenological citizens are nonplussed, as Dr. Zukertort is said to have no especial development of locality or individuality. The psychology is possibly no more difficult than that of a retentive memory for words; Dr. Zukertort's is for forms, pictures, and changes. I have been told by a very skilful player that he can play almost any number seeing, that there are certain openings and certain rules for moving, and that they most assist in remembering the changes and position of the pieces. To a casual observer his most wonderful feat is that of repeating, as I witnessed, all the moves of himself and opponents in a series of games played several hours before, and without a single mistake. It is quite evident that a remarkable memory for positions and combinations is required for such feats, and persons not having that memory could not by any practice excel any more than a dull prosaic man could by practice become a poet. Memory, concentrativeness, judgment, and locality appear to be at the base of Dr. Zukertort's very fine blindfold and ordinary playing.

DEATH FROM THE EFFECTS OF MORPHIA.

The city coroner held an inquest at the Infirmary, Carlisle, upon the body of a farm-servant, on Nov. 29th, the young man having died the same morning. It appears he was admitted to the infirmary on the previous Thursday suffering from a lacerated hand, sustained while working at a threshing machine, which necessitated amputation at the wrist. Under the influence of ether this was done on the Friday, and he appeared to have borne the operation well. The same evening it was deemed advisable to give him a subcutaneous dose of morphia, and by direction of the house-surgeon the resident pupil injected a quarter of a grain of morphia about half-past ten at night. About a quarter to six o'clock on the next morning the nurse on duty observed such a change in the patient's appearance that she called up the house-surgeon. The man was found to be in a dying state, and evidently from the effects of morphia. The medical evidence attributed the cause of death to some peculiarity in the system, causing morphia in such a dose to take an unusual effect. The jury returned a verdict of "Death while under the influence of morphia," adding that no blame could be attributed to any one.

GATESHEAD DISPENSARY.

This week an election took place for the vacant office of house-surgeon at the Gateshead Dispensary, when the choice of the governors fell upon Dr. Robert Hardie of this city, who was selected from a list of fifty-eight candidates. The salary is, I am told, 200 guineas per annum with apartments, and some other advantages; but I believe the appointment has been heretofore principally sought as a capital and legitimate stepping-stone to general practice.

SMALL-POX IN DURHAM.

The medical officer in charge of the small-pox hospital in the city of Durham states that since the hospital was ready for patients (November 13th) the total number of cases admitted was sixty-three, ten of whom have been discharged well. There are now in hospital forty-nine patients, six of whom are convalescent. The usefulness of the Barracks Small-pox Hospital is being constantly demonstrated, its efficient management and kind treatment of patients having obviated all reluctance to enter it by persons when stricken with the disease. The disease is also reported as having appeared in the neighbouring towns and villages, including Bishop Auckland, Lanchester, Chester-le-Street, &c.

THE DISTRESS IN THE NORTH.

The distress in the north arising from want of employment shows as yet no signs of abatement, and it is much to be feared that our working classes here will have a bad time of it this winter. So far, the weather has been generally mild, which is a very great advantage to the poor. From Sunderland and other of our maritime towns, where so much depends on shipping and shipbuilding, complaints are very loud. The private efforts to mitigate the wants of the poor are most praiseworthy and persistent, and, except in the township of Southwick, Sunderland, I do not hear of any unusual amount of illness. At Southwick, however, principally owing to epidemics of measles and scarlatina, the mortality amongst children has been excessive.

Newcastle-upon-Tyne, Dec. 10th.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS.

AT present the Examiners of this College are prohibited from being either private teachers or lecturers; but as it is thought that this may prevent otherwise eligible candidates from coming forward, an alteration of this rule, so far as lecturers are concerned, is by some thought advisable. A good deal may be said on both sides of the question, but the matter must be fully discussed and brought before the Fellows for their sanction before the proposed change can be adopted.

QUEEN'S COLLEGE, CORK.

The President, in his annual report recently issued, states that the total number of new students for the academic session 1883-4 was 67, and that the total number on the books of the College for the session was 298, of whom 278 were matriculated and 20 non-matriculated. As was expected from the disturbing effects of the dissolution of the Queen's University and the establishment of a new University with which the College had no official connexion, the number of new students last session was smaller than that of the preceding year, when, as was pointed out in the last report, the number had been abnormally increased by the premature entrance of a number of students who had been preparing for the College in order that they might secure the protection provided by the Act of Parliament for students of the Queen's Colleges. The total number of students was, however, considerable when we take into account the disorganising effects of the recent changes and the uncertainty and doubt created in the minds of students about to commence their University studies.

DUBLIN HOSPITAL SUNDAY.

It is believed that the collections made last month for the Dublin hospitals have been very successful, and that a considerable increase on the previous year may be confidently expected. In 1883 the sum realised amounted to £4212, and this year it is thought that £4500 may be obtained.

CASE OF ACCIDENTAL POISONING.

A Poor-law guardian named O'Dwyer, of Bansha, Tipperary, died recently from taking in mistake a dose of ammonia and camphor, which was intended to be used as a liniment. Although the medical practitioner gave verbal directions, he neglected to place a label on either bottle. The coroner's jury brought in the usual verdict of "Accidental death," and no one to blame for the occurrence.

MATER MISERICORDIÆ HOSPITAL, DUBLIN.

On last Sunday a meeting took place at this hospital for the purpose of obtaining funds to build a new wing, at an estimated cost of £18,000. In 1871 the western wing was completed, and the eastern wing, which it is now proposed to erect, will provide the accommodation which is found to be so urgently required. This will include a maternity and school for training midwives. The subscriptions promised at the meeting amount to upwards of £1000.

BEQUESTS TO MEDICAL CHARITIES.

The late Mr. Robert Billing, of the County Dublin, bequeathed £15,000 to the following charitable institutions—viz.: The Meath Hospital for Incurables and City of Dublin Hospitals, £3000 each; Rotundo Lying-in, Adelaide, and Cork-street Fever Hospitals, £2000 each. The late Mr. Gorman left nearly £50,000 to various charitable institutions in Dublin, but as the will is disputed the case will be tried on the 23rd proximo.

Digitized by Google

ENTRIES AT THE DUBLIN MEDICAL SCHOOLS.

In last week's issue, by a printer's error, the number of students who have entered for the present session were stated to have shown a decrease of nine as compared with last year. It should have been an increase of one.

Dr. McIntyre, late medical officer of Coleraine dispensary district, has been refused a retiring allowance by the guardians; Dr. Traill has given notice of motion to rescind the resolution of the board but as the matter has been decided on three occasions I fear that there is but slight hope of a satisfactory settlement.

Dublin, Dec. 9th.

PARIS.

(From our Paris Correspondent.)

DEATH OF M. MORIN.

M. MORIN, whose case was reported in my letter of last week, died on Sunday night about half past ten o'clock. The slight improvement that was noticed in the latter part of my letter was not maintained, for he gradually got worse, and on Sunday morning the thermometer marked 41° C. in the axilla. The patient seemed not to have lost his consciousness entirely, for although unable to speak he followed with his eyes the movements of the surgeon who was dressing his wounds for the last time on the morning of the day of his death, and appeared to be grateful for what was being done for him. At noon of the same day his body was covered with a cold perspiration. About 10 A.M. vomiting had set in. At 6 P.M. the patient was still conscious, and seemed to recognise the Sister of Charity and others who were attending him. He drank with avidity all that was given him, which, however, was immediately rejected. The pangs of death began soon after this, and although the patient would be regarded by some as a worthless character, yet those who surrounded him in his dying moments were much affected by his sufferings, and felt that death would be a relief to him. His body has been removed to the Morgue, where it will be subjected to examination, and in all probability the question will arise as to whether death was caused by bullet wounds or by the effects of the operations. Since her incarceration Madame Clovis Hugues, the heroine of the tragedy, has been making daily inquiries respecting the condition of her victim, and on hearing of his death was very much affected. She has since been in a depressed state of mind, at which one cannot be astonished.

INQUIRY INTO THE NATURE OF CHOLERA.

I have just received a circular letter signed M. Camescasse, Prefect of Police, forwarding a paper containing a series of questions with the view of elucidating, if possible, the nature of cholera and the origin of the late epidemic of the disease in this country. The questions which have been forwarded to every medical man in the French territory have been drawn up by a Commission of the Academy of Medicine, composed of MM. Besnier, Brouardel, Fauvel (since died), Noël-Guéneau de Mussy, Legouest, Marey, Pasteur, Proust, and Rochard. The paper is drawn up somewhat on the principle of the collective investigation system employed in England, but would be too long to be transcribed here. I may, however, give some of the heads on which the answers to the questions are to be based. In the preface of the report of the Commission it is observed that it has been ascertained from documents referring to previous epidemics that the transmission of cholera may be effected in different ways, but which do not present the same degree of danger. The contagious element seems to reside particularly in the fæcal matter, but its potency is altered according to the vehicle which conveys it. The handling of linen soiled by choleraic dejections, the drinking of water contaminated by such dejections, constitute two sorts of danger, the reality of which is demonstrated by numerous observations, and against which we must be on our guard. It is of the greatest importance to fix the duration of the stage of incubation of cholera, for the protection afforded by quarantine measures can only be efficacious if the latter are based on the knowledge of the maximum of this duration. The minimum duration is equally important to know, with the view of ascertaining as to whether any aggravation in the intensity of an epidemic could be connected, as cause and effect, which might have preceded it at a longer or shorter interval, such as the appearance of a storm, &c.

THE WATERS OF LA BOURBOULE.

In my letter headed "French Health Resorts," which was published in THE LANCET of Nov. 8th, I mentioned that the waters of La Bourboule contained as much as twenty-seven milligrammes of arsenic to the litre. I have since learned that this is an error. They are stated to contain seven milligrammes of the metalloid, and twenty-eight milligrammes of the arseniate of soda, or ten milligrammes of arsenious acid.

ELECTIONS AT THE ACADEMY OF MEDICINE.

Dr. Bergeron has been elected Vice-President of the Academy of Medicine, in the room of Dr. Fauvel, deceased; and Dr. Charpentier, Member in the Section of Obstetrics, in succession to the late Professor Depaul.

NECROPSY OF M. MORIN.

The post-mortem examination of the body of M. Morin was performed yesterday by Professor Brouardel, the Medical Jurist, in the presence of the Procureur of the Republic and other judicial authorities. The examination confirmed the different points referred to in my letter of last week, with the exception that a fragment of the bullet which struck the skull was found lodged in the meninges. Meningo-cerebritis was the result, and this was stated to be the immediate cause of death. The bullet, which entered the throat and lodged above the left clavicle, was found lower down in the chest. It was of the calibre 7 mm. = bore ·297 of the English scale, and was handed to M. Gastyne-Renette, a gunsmith, who was summoned as an expert for the prosecution. Madame Clovis Hugues was exempted from being confronted with the corpse, as is usual in such cases, owing to the delicate state of her health.

Paris, Dec. 10th.

Obituary.

DANIEL J. DUIGAN, C.B.,

DEPUTY INSPECTOR-GENERAL OF HOSPITALS AND FLEETS.

DR. DUIGAN, who died on the 2nd inst., at the age of sixty-three, belonged to an old and much-respected family in Kilkenny. He was educated in Dublin, and took the F.R.C.S.I. in 1845, the M.D. of Aberdeen in 1857, and the M.R.C.P.L. in 1860. He entered the naval service in 1844, and was employed for a year at Haslar Hospital, after which he served for seven years in the Mediterranean in the *Hibernia* and *Queen*, flagships of Admiral Sir William Parker, G.C.B. In December, 1853, he was appointed to the *Royal George*, whence he was transferred, in April, 1854, to the *Duke of Wellington*, and was engaged in the Baltic, in the operations at Bomarsund, during the Russian war, being in all the most important boat operations by night and day, as well as in the assaults on batteries, in which his conduct gained the approval of Sir H. Jones, the commanding engineer. On returning to England he was ordered to join the Naval Brigade before Sebastopol, and to take passage in the *Prince*. He escaped the dreadful fate of his fellow-passengers by his alacrity in proceeding ashore to his appointment immediately the *Prince* arrived at Balaclava, on the eve of the total wreck and disappearance of that ship. Through the terrible winter 1854-55 he served in the camp of the Royal Naval Brigade, as surgeon in charge of its second division hospital. On the return of spring, with the reopening of bombardments, he volunteered for service in the batteries and trenches, being the only officer of his rank on leaving England who was in that position; having from that time until the fall of Sebastopol, on the 8th of September, been present in the batteries on the opening day of every one of the three great bombardments. On the fatal 10th of June, being confined to his tent by a severe attack of camp fever, he rose from his bed and proceeded at dawn to his proper post in the Diamond battery under Sir William Peel's command, whose admiration he excited for his steady attention to the sufferers during that eventful day. His valour was equally conspicuous on the closing day of the siege; in fact, it may be said he was ever on the alert to be present at the

Digitized by Google

point of danger, and was never behind time there. For these services he obtained the Sebastopol medal, the fifth class of the Order of the Medjidieh, and lastly the decoration of Companion of the Order of the Bath, and the Sardinian and Turkish medals, with clasp. He subsequently served in the *Vulture* in the Mediterranean from 1858 to 1860; in the *Mersey* on the North American and West Indian station from 1860 to 1862, and at the Jamaica Naval Hospital for five years (1862 to 1867). He was employed with the Royal Marines at Deal from May, 1867, to July, 1870, and in the *Agincourt* from August, 1872, to February, 1874, when he was appointed to Devonport dockyard, which appointment he held until he was placed on the retired list, with the honorary rank of Deputy Inspector-General, in April, 1876.

Always exemplary for his kind, gentle, and courteous demeanour to all around him, for his unswerving zeal and attention to his duties, and for his oft-repeated acts of self-denial, he was esteemed by his nearest friends and companions in arms as a gentleman and officer in a truly classical sense—"Factus ad unguem." He has left a widow, two sons and a daughter, with family and friends to lament their loss.

LLEWELYN THOMAS, M.D.

LLEWELYN MORGAN THOMAS, who died on the 26th ult. at the early age of thirty-six, was educated at Dulwich School, whence he proceeded to St. Thomas's Hospital. He gained the Cheselden medal and scholarship, and on qualifying filled the office of house-surgeon and resident accoucheur. Having taken a voyage to China with the Submarine Cable Company's expedition, he became resident medical officer at the Guest Hospital, Dudley, for two years, on leaving which he was presented with a testimonial of regard. Having graduated as M.D. of Brussels, with honours in operative surgery, he settled in London about ten years ago as a specialist in throat and ear diseases, and quickly attained reputation and a good practice, as is evident by the fact that he was physician to three large institutions connected with education of the vocal and musical arts—namely, the Royal Academy of Music, Trinity College, and the Guildhall School of Music. He was also honorary aurist to the Jews' Deaf and Dumb School, and surgeon from its foundation to the Central London Throat and Ear Hospital. Although Dr. Thomas had not written much, his short essays on Diseases of the Throat and Ear, published by Churchill, were full of practical suggestions, and his opinion was valued by his colleagues as one full of sound judgment. His great devotion to his art and his extreme amiability endeared him to his patients, his colleagues, and all with whom he came in contact. The cause of his death was acute nephritis, the symptoms of which only manifested themselves three days before the fatal termination. It was characteristic of him that, although he was aware that for many months, probably years, he was the subject of Bright's disease, he had kept it to himself rather than give anxiety regarding his health to his family.

CHARLES WADSWORTH, L.R.C.P., L.R.C.S. ED.

IT is with extreme regret that we announce the death of Mr. Charles Wadsworth, which took place at his residence in Belfast on the 3rd instant. While in the discharge of his duties he contracted typhus fever (a malady to which so many Irish physicians have succumbed), and after a very severe attack he died on the twelfth day, at the early age of thirty-four. After having studied at the Belfast Medical School, Mr. Wadsworth obtained the qualification of Licentiate of the Royal Colleges of Physicians and Surgeons of Edinburgh in 1873, and commenced practice in Belfast, where he was appointed one of the district dispensary doctors. As a student Mr. Wadsworth was well known at the principal Irish athletic clubs as a most enthusiastic and very popular athlete, he having few equals at throwing the hammer and putting the weight. As a medical man Mr. Wadsworth was much respected by a wide circle of patients and friends, and at the last election of officers of the Ulster Medical Society he was chosen one of the vice-presidents. His funeral took place on Friday, 5th inst., when almost all the medical men in town were present. At a meeting of the Dispensary Committee, held on Monday, Dec. 8th, it was agreed to transfer Dr. Clements from his own dispensary district to that held by the late Mr. Wadsworth, while Dr. Torrens was also transferred to the district held by the late Dr. Martin. The election to fill the vacancies caused by these transfers will take place in a fortnight.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council held on Thursday last Mr. Hulke was re-elected a Member of the Court of Examiners; and Messrs. Langton and Pick were elected Members of the Court, *vice* Messrs. Cooper Forster and Savory resigned.

The Nomination Committee presented its report on the candidates for the several examinerships to be appointed by the College of Surgeons under the combined scheme of the two Colleges. The following elections were made:—

Elementary Anatomy: Messrs. J. N. C. Davies-Colley, A. P. Gould, C. W. M. Moullin, J. Black, and R. W. Reid.

Elementary Physiology: Mr. C. H. Golding-Bird.

Anatomy: Messrs. H. G. Howse, E. B. Owen, R. J. Godlee, and W. H. Bennett.

Physiology: Messrs. H. Power, W. M. Baker, and G. F. Yeo.

Midwifery: Drs. Galabin and Champneys, and Messrs. G. E. Herman and W. A. Duncan.

On the recommendation of the Nomination Committee, the following Fellows were elected members of the Board of Examiners in Anatomy and Physiology for the Fellowship of the College for the ensuing year:—

Anatomy: Messrs. Howse, Anderson, Owen, Godlee, and Morris.

Physiology: Messrs. Power, Baker, Golding-Bird, and Yeo.

Mr. Marshall's motion to reduce from twenty guineas to fifteen guineas the fee for the Diploma of Member of the College, when granted under the combined examinations of the two Royal Colleges, was postponed.

Sir James Paget, Mr. Erichsen, Sir Spencer Wells, Mr. Marshall, together with the President and two Vice-Presidents, were appointed delegates of the College to confer with an equal number of delegates of the Royal College of Physicians, respecting the arrangements whereby the two Colleges may become joint tenants of a site in Long-acre whereon to build rooms for examinations and other purposes.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members, having passed the Final Examination for the Fellowship on Nov. 27th, 28th, 29th, and Dec. 1st, were, at a meeting of the Council held on the 11th inst., admitted Fellows of the College:—

Bishop, Edward Stanmore, L.R.C.P. Ed., Albany Chambers, Manchester; Diploma of Membership dated July 26th, 1871.
Anderson, Alexander R., L.S.A., General Hospital, Nottingham; January 24th, 1877.
Morse, Thomas H., L.R.C.P. Ed., Prince of Wales-road, Norwich; November 20th, 1879.
Jessop, W. Hamilton Hyison, M.B. Camb., Harley-st., July 27th, 1880.
Johnson, Geo. Lindsay, M.B. Camb., Fernlea, Highfield-hill, Upper Norwood; January 24th, 1881.
White, Edwin Francis, L.S.A., Dealtry-road, Putney; April 21st, 1881.
Tait, Henry Brewer, L.R.C.P.L., Highbury-park, July 21st, 1881.
Pounds, Thomas Henderson, L.S.A., Snodland, near Rochester; July 22nd, 1881.
Cahill, John, L.R.C.P.I., Albert Gate; July 27th, 1881.
Colville, Ernest George, College-road, Eastbourne; Nov. 18th, 1881.
Dendy, Walter Chester, L.R.C.P.L., Chaplin Villa, Forest-hill; November 19th, 1881.
Hewer, J. L., M.B. Lond., Highbury New Park; Jan. 19th, 1882.
Watson, Archibald, M.D. Paris, Queensland; Jan. 23rd, 1882.
Bull, W. Charles, Bromborough, Cheshire; April 19th, 1882.
Howard, Robert Jared Bliss, L.R.C.P.I., Montreal, Canada; July 31st, 1882.
Wilson, James, M.D. Q.U.I., Money More, Derry; May 14th, 1883.

Two other candidates passed the examination, but not having attained the legal age (twenty-five) will receive their diplomas at a future meeting of the Council. Twelve candidates failed to reach the required standard, and were referred to their professional studies for one year.

The following gentlemen, having previously passed the required examination in Surgery and having obtained the

Digitized by Google

necessary Medical qualification, were admitted Members of the College on the 1st inst. :—

Dickinson, Joseph Jewitt, L.S.A., Bow-road.
Gray, Thomas Underwood, L.R.C.P.L., Essex-road.
Mullis, George William, L.S.A., Derngate, Northampton.

CAMBRIDGE UNIVERSITY.—At a congregation held on the 4th inst., the following degrees were conferred :—

DOCTOR OF MEDICINE.—John Mackern, Gonville and Caius.
BACHELOR OF MEDICINE,—Harold Bailey Shaw, Sidney Sussex.

UNIVERSITY OF DURHAM.—At the recent examinations for degrees in Medicine and Surgery, the following candidates satisfied the Examiners :—

DOCTOR IN MEDICINE FOR PRACTITIONERS OF FIFTEEN YEARS' STANDING.

Coombs, Rowland Hill, L.R.C.P., M.R.C.S., L.S.A.
Martin, William Young, F.R.C.S.

DOCTOR IN MEDICINE (THESIS).

Robinson, William, M.B., M.S., M.R.C.S.
Sheppard, William John, M.B.
Squance, Thomas Coke, M.B., M.S.

BACHELOR IN MEDICINE.

Blackwood, Fredk. Martindale, M.R.C.S., College of Medicine, Newcastle-upon-Tyne.
Davidson, Charles Robert, Westminster Hospital.
Erulkar, Solomon Abraham, Grant Medical College, Bombay, and College of Medicine, Newcastle-upon-Tyne.
Harper, Alexander, M.R.C.S., St. Bartholomew's Hospital.
Malden, Frank James, St. Bartholomew's and College of Medicine, Newcastle-upon-Tyne.
Mears, Frederick Charles, M.R.C.S., L.S.A., London Hospital.
Newbolt, George Palmerston, St. Bartholomew's Hospital.
Pollard, Reginald, St. Bartholomew's Hospital.
Richards, George William, London Hospital.
Slater, William, College of Medicine, Newcastle-upon-Tyne.
Tanner, Charles Edward, M.R.C.S., St. Bartholomew's Hospital.
Wakefield, Mark J., College of Medicine, Newcastle-upon-Tyne.
Watson, James Russell, M.R.C.S., Charing-cross Hospital.
Wigham, William H., College of Medicine, Newcastle-upon-Tyne.

MASTER IN SURGERY.

Irvine, Robert J., M.B.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Dec. 4th :—

Barrett, William Amherst Henry, St. Thomas's Hospital.
Cory, Isaac Rising, St. Thomas's Hospital.
Gray, John Alfred, St. Bartholomew's Hospital.
Martin, Francis George Clifton, London Hospital.
Oldham, Montague Williams, Guy's Hospital.
Relton, Bernard, St. Thomas's Hospital.
Sydenham, George Francis, St. Bartholomew's Hospital.
Wade, Charles Henry, London Hospital.
Yeoman, Charles, St. Thomas's Hospital.

The following gentlemen also on the same day passed the Primary Professional Examination :—

Samuel Constable, Dublin and St. George's Hospital; Edward Soy King's College.

AN anonymous donor has given £1000 to the Swansea Hospital.

ON the 6th inst., Mrs. Gladstone opened a Maternity Home in Shadwell.

THE Library of the Royal College of Surgeons of England will be closed on Friday and Saturday the 26th and 27th inst.

A STRANGE FREAK.—A man was recently admitted into the City of Dublin Hospital who had swallowed seventeen half-sovereigns.

THE Fancy Fair in Glasgow, held with the object of raising sufficient funds to build a sick children's hospital, closed on the 29th ult., the sum obtained being £20,011.

VACCINATION GRANT.—Dr. Horace Lowther, of Ventnor, has been awarded the Government grant for efficient vaccination in his district.

THE Corporation of Reading has approved the erection of a one-storey building for use in the isolation of cases of scarlet fever, and of a public mortuary for the town, at a total cost of about £700.

ON the 17th ult., on the occasion of the newly elected Mayor of Stockport attending divine service in state, the collection on behalf of the local infirmary amounted to £130.

SUPERANNUATION.—Mr. George Bland, L.R.C.P., L.R.C.S.Ed., late medical officer for the Eastchurch district and the workhouse of the Sheppey Union, has been awarded a superannuation allowance of £50 a year.

AT a tea party at Oldham last week some twenty of the guests were attacked with serious illness. All the sufferers were said to have partaken of cured tongue which had been enclosed in a tin vessel.

THE Leicester Board of Guardians have, we understand, decided to proceed with the prosecution of defaulters under the Vaccination Acts. This will be no light task, as the malcontents are said to number about 4000.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The third meeting of the twenty-ninth session, 1884-85, was held at the Royal Kent Dispensary, Greenwich-road, on Friday evening, the 5th inst., when Dr. Horrocks, of Guy's Hospital, read a paper on "Inflammation of the Cervix Uteri."

A MUNIFICENT BEQUEST TO SYDNEY UNIVERSITY.—The Sydney University has just become entitled to a bequest of £180,000, in accordance with the terms of the will of Mr. Challis, a wealthy colonist, who has adopted this mode of perpetuating his memory.

AN inquest was held recently at Hatfield on the body of Mr. Charles Wade, surgeon, who died suddenly on the 28th ult., whilst present at an entertainment. The jury, having heard medical evidence to the effect that death was due to fatty degeneration of the heart, returned a verdict accordingly.

HOSPITAL SATURDAY FUND.—At a meeting on Wednesday last of the delegates of this fund, regret was expressed that the majority of participating institutions still refuse to open their doors to applicants for relief during the evening, when working people could attend without loss of valuable time.

THE ROYAL HOSPITAL FOR INCURABLES.—The annual meeting of the governors and subscribers of this charity was held on the 28th ult. The secretary stated that financially the past year had been a prosperous one, the total income as compared with the previous year showing an increase of £6731. In November of last year the number of beneficiaries of the hospital was 654, and 50 have been since elected.

GLASGOW WESTERN INFIRMARY.—The tenth annual general meeting of the supporters of this institution was held on the 27th ult. The number of out-patients treated during the year was 22,039, as compared with 18,905 in the previous twelve months; and of in-door patients 3777, as against 3927. The ordinary income for the year amounted to £13,359, while the expenditure was £18,589. The extraordinary income consisted of £14,433 derived from legacies.

THE death has recently occurred of Dr. Augustus Voelcker, F.R.S. Educated at Göttingen the deceased came over in early life to England, and successively held the posts of assistant to the late Professor Johnston at Edinburgh, Professor of Chemistry in the Royal Agricultural College at Cirencester, and Professor of Chemistry to the Royal Agricultural Society of England. He was well known as the author of several works on theoretical and agricultural chemistry, such as the "Chemistry of Food" and the "Chemistry of Manures."

THE INVENTOR OF THE TELEGRAPH.—On August 27th a deputation from the Royal Society of Victoria waited upon the Premier of the Colony with the view of urging the claims of Dr. Davy as an inventor of the electric telegraph on the attention of the Government. It was finally decided that, pending the endeavour of the Premier to obtain the insertion by the Home Government of Dr. Davy's name in the civil list, a motion should be made in the legislative assembly for £100 to be placed on the estimates this year for Dr. Davy, the Government undertaking to support the motion.

CLINICAL, MEDICAL, AND GENERAL LIFE ASSURANCE SOCIETY.—The sixtieth annual general meeting of this Society was held on the 28th ult., when a very satisfactory report was presented. The three completed years of the current quinquennium show, when compared with those of the previous period, that while the new business has been substantially greater, the revenue has increased in an augmented ratio, and the additions to the assurance fund have been larger, the death claims relatively to the sum assured, and the working expenditure proportionately to the income, have been less.

Digitized by Google

HEALTH CONFERENCE IN MANCHESTER.—A meeting was held in Manchester on the 5th inst., for the purpose of making arrangements for holding a conference in that city next Easter, on subjects connected with health and education. Among the subjects proposed for discussion are overpressure, cheap meals for school children, the protection of the sight, the spread of disease in schools, and the means of isolation.

THE PARKES MUSEUM OF HYGIENE.—The ordinary general meeting of the members of the Parkes Museum was held on the 4th inst. The report set forth the work done in connexion with the Museum during the past year, which had included lectures by the Council of the Sanitary Assurance Association, in addition to those arranged by the Council of the Museum. The accounts showed that there was urgent need for increased subscriptions if the Museum was to be continued, for the small invested capital had had to be made use of this year to meet the current expenses. On Wednesday the second of the series of three popular lectures on "Precautions against Cholera" was given by Mr. Shirley Murphy, medical officer of health for St. Pancras, particular attention being drawn to this lecture to the subject of local precautions.

THE HOSPITALS ASSOCIATION.—The session of 1884–85 was opened with a soirée at the rooms of the Medical Society of London, on Saturday evening last, when there were present the lady superintendents and secretaries of most of the principal hospitals in the metropolis, besides other distinguished guests, and a very enjoyable evening was spent. The attractions included music and recitations, and a short address by Major Ross, M.P., the chairman of the Council. The first general meeting of the Association will be held on the 17th inst., Dr. Buchanan, F.R.S., presiding, when Professor Marshall, F.R.S., will deliver a lecture on "Hospital Circular Wards," and Mr. Keith Young will read a paper entitled "A short Description of the Miller Memorial Hospital," which hospital will be opened the same day at Greenwich.

PRESENTATIONS.—Dr. R. D. Williams was recently presented with an illuminated address and a salad bowl by the employés of the Landove Tin Scale works on the occasion of his marriage.—Dr. Daxon, of Ennis Lunatic Asylum, has, on his retirement, been presented with an address and a valuable clock by the officers and attendants.—Dr. Peregrine has been presented, on the occasion of his departure from Silchester, with an ebony inkstand, as a mark of the esteem in which he and his family are held.—Dr. Dodds, who has been appointed Deputy Superintendent of the Montrose Asylum, was presented on the 28th ult. with a handsome timepiece by the officers and staff of the Birmingham Borough Asylum. The presentation was made by the superintendent on behalf of the subscribers, who spoke in the highest terms of Dr. Dodds. The timepiece was of black marble in the shape of a temple, striking the hours and half-hours on a gong.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BLACKMORE, ALFRED, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the First District of the Manchester Township.

CLARKE, JAMES ADAMS, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Busney District of the Watford Union, vice Hicks.

COSGRAVE, E. MACDOWEL, M.D., Ch.M., L.K.Q.C.P.I., L.R.C.S.I., has been appointed to the Chair of Botany and Zoology in the Carmichael College, Dublin.

DE'ATH, ROBERT, M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Borough and Union of Buckingham.

DODDS, W. J., M.D., D.Sc, has been appointed Assistant Medical Superintendent to the Montrose Royal Lunatic Asylum.

FOX, W. PIERCY, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Resident Medical Officer to the Rochdale Infirmary, vice Herbert M. Gay, M.B., resigned.

GOULD, A. PEARCE, M.S.Lond., F.R.C.S.Eng., has been appointed Surgeon to the Hospital for Epilepsy and Paralysis, Regent's-park, vice Prof. Godlee, resigned.

GUBB, ALFRED S., M.R.C.S., late Resident Obstetric Assistant at Westminster Hospital, has been appointed Resident Medical Officer to the French Hospital, Leicester-square.

HALL, ALFRED, M.R.C.S., has been appointed Medical Officer for the Calton District of the Ashbourne Union, vice J. B. Hall.

LAMB, WILLIAM, M.D., C.M.Ed., has been appointed Medical Officer for the Arnold District of the Basford Union.

LANGFORD, HENRY EDWARD, M.D.Ed., M.R.C.S., has been appointed Medical Officer for the Kidderminster No. 2 District of the Kidderminster Union, vice Roden.

MOORE, ADAM JAMES, M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer for the Parish of St. Lawrence, Reading Union.

PRAGER, ISIDORE FRED., L.D.S., L.R.C.S.I., late Assistant House-Surgeon, has been appointed House-Surgeon to the National Dental Hospital.

RUNDLE, EDMUND, L.K.Q.C.P.I., L.R.C.S.I., L.M., of Porthleven, has been appointed Medical Officer and Public Vaccinator for the newly-formed District of Lithney, in the Helston Union, Cornwall.

SCOTT, CHARLES CASELY, M.B., C.M.Ed., has been appointed Medical Officer for the Isleworth District of the Brentford Union, vice Hunter, deceased.

STRUGNELL, WALTER T., M.R.C.S., L.S.A.Lond., has been appointed House Surgeon to the Great Northern Central Hospital, Caledonian-road, N., vice F. A. Stokes, M.R.C.S., resigned.

SUFFERN, A. C., M.D., M.Ch., has been appointed Assistant Medical Officer to the Borough Asylum, Winson-green, Birmingham, vice Dr. Dodds, resigned.

SYMONS, J. GEO. RENNY, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Third District of the Holsworthy Union, vice Pearce.

WILLIAMS, P. WATSON, L.R.C.P., has been appointed Clinical Assistant to the Birmingham Borough Asylum, vice J. D. Bush, resigned.

Births, Marriages, and Deaths.

BIRTHS.

CUFFE.—On the 8th inst., at Dundalk, the wife of Surgeon-Major C. McDonogh Cuffe, C.B., Medical Staff, of a son.

HOWLETT.—On the 7th inst., at 4, Wright-street, Hull, the wife of E. H. Howlett, F.R.C.S., of a son.

MASON.—On the 6th inst., at Bear Tree House, South Ockendon, the wife of A. Haynes Mason, L.R.C.P., of a daughter.

MOORE.—On the 2nd inst., at Bareilly, India, the wife of Surgeon-Major J. H. Moore, Medical Staff, of a son.

REYNOLDS.—On the 7th inst., at Stamford-hill, N., the wife of W. Percy Reynolds, L.R.C.P.Lond., M.R.C.S., of a daughter.

SKEEN.—On the 28th ult., at Patiála, Punjab, the wife of Surgeon-Major A. Skeen, M.B., I.M.D., of a daughter.

WHITING.—On the 2nd inst., at Ebury-street, Eaton-square, S.W., the wife of James D. C. Whiting, M.R.C.S., of a son.

MARRIAGES.

ROW—DEMPSTER.—On the 26th ult., at Stoke Dameral Church, Devonport, Frederick Everard Row, M.R.C.S., L.R.C.P.E., son of Fredk. Row, M.D., J.P., to Eleanor Elizabeth Carroll (Nella), eldest daughter of the late James Carroll Dempster, M.D., Deputy Surgeon-General, A.M.D.

SPOONER—ARCHER.—On the 2nd inst., at St. John's Church, Hackney, Fred. H. Spooner, M.D., of Howard House, Clapton, to Jane Levesque, eldest daughter of Thos. Archer, Esq., F.R.H.S., of Kenninghall-road, Clapton.

WILDE—MARTIN.—On the 6th inst., at St. John's, Crawley, Sussex, by the Rev. J. Barrett Lennard, M.A., Frederick Wilde, M.R.C.S., to Margaret Helen, second daughter of T. H. Martin, M.R.C.S., of Crawley.

WILSON—WILSON.—On the 4th inst., at St. Michael's Church, Headingly, Samuel Wilson, M.R.C.S., L.S.A.Lond., of Mare-street, Hackney, to Hannah, youngest daughter of the late Joseph Wilson, Esq., of Melville House, Batley, Yorks.

DEATHS.

BANISTER.—On the 6th inst., at Eastbourne, George Banister, late Surgeon-General, Indian Army, aged 64.

DUIGAN.—On the 2nd inst., at his residence, Edith-road, West Kensington, Daniel John Duigan, C.B., M.D., Deputy Inspector-Gen. of Hospitals and Fleets, R.N., in his 63rd year.

GIBSON.—On the 5th inst., at his residence, 9, River-street, Myddelton-square, E.C., John Billerwell Gibson, M.R.C.S., aged 73.

LAY.—On the 4th inst., at Peasenhall, Suffolk, Joseph John Lay, M.D., M.R.C.S., L.S.A.Lond., aged 70.

MUSCROFT.—On the 5th inst., at Pontefract, Henry Muscroft, M.D., in his 55th year.

ROBERTSON.—On the 2nd inst., at Bath, James Robertson, M.D., M.R.C.S., F.L.S., &c., formerly of the City of Rochester, aged 45.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

ASPIRATOR FOR REMOVING EXUDATIONS FROM THE TRACHEA AFTER TRACHEOTOMY, &c.

To the Editor of THE LANCET.

SIR,—A very simple and inexpensive form of aspirator has occurred to me for the removal of diphtheritic and croupy exudations from the trachea after tracheotomy, and indeed, I think it might be used in many other cases in which aspiration is required. I claim for its merits, first, that it is easily procured, in fact, it may be extemporised on the spot; secondly, that it is efficacious; and thirdly, that it may be constructed by any instrument maker and supplied by him at a very small cost, as no air-pump, syringe, or other costly mechanism is required. The apparatus consists of an exhausted bottle, and I think my method of obtaining the desired vacuum is unique. We have in the usual quart aerated water bottle with syphon tap, as supplied by most chemists and aerated water dealers, all the apparatus that is required, with the exception of a foot or two of rubber tubing, and two or three metal unions made to fit the different sized tracheotomy tubes. The rubber tube is slipped over the tap and one of the unions is affixed to its other end. To produce the vacuum, the bottle is immersed in a large tin saucepan or other suitable vessel, containing sufficient warm water to cover the bottle up to its neck. The water, with the bottle thus immersed, is then brought to the boiling-point, by placing the vessel over the fire, the syphon tap being kept open to allow of the escape of the expanded air. The bottle is retained in the boiling water until air ceases to escape from the tap; this may be ascertained by occasionally closing and re-opening the tap; when air ceases to escape, the bottle is removed from the boiling water, and placed aside to cool, with the tap closed. When it has cooled a vacuum will have formed possessing great suction power. This may be tested by immersing the open end of the rubber tube in water and then opening the tap, when the water will rush into the bottle with great force and will about three parts fill it. Here then we have a ready and simple method of clearing the trachea by aspiration. The apparatus can be made by anyone in a case of emergency, with an ordinary bottle having a closely fitting perforated cork through which passes a piece of glass tube; perhaps even a Maw's feeding bottle might answer the purpose.—I am, Sir, yours truly,

R. W. SUTTON BARRACLOUGH, M.D.

Dulwich-road, Herne-hill, S.E.; Dec. 1st, 1884.

Mrs. Hoare.—The letter was received and referred to in an annotation in our issue of Nov. 29th.

CHARBON.

To the Editor of THE LANCET.

SIR,—The publication in your last issue of two cases of charbon with a reference to the practice of excision induces me to ask the attention of your readers to the excellent account of this disorder, and its successful treatment by excision, given at page 371 in Travers' work on Irritation. The date of the cases there mentioned is 1796.

I am, Sir, yours faithfully,

Old Burlington-street, W., Dec. 5th, 1884. J. W. HULKE.

INSPECTOR-GENERAL CORBIN.

WE have been asked to publish the following:—

"M.G.O." "Asst.-Adj.-Gens. Office, R.G.M., 20th Nov., 1884.

"The Lieutenant Governor regrets to find himself under the obligation of accepting Inspector-General M. A. B. Corbin's application to be relieved from active duties with the militia force. Commencing as an assistant surgeon in the Artillery Brigade, he terminates his services as the head of his department, embracing altogether a period of more than half a century, during which he has always ably and punctually carried out the duties of the medical department. His Excellency feels convinced that the militia force will join with him in thanking Inspector-General Corbin for his long service, and in wishing him health and happiness in his retirement. Inspector-General Corbin's name will be placed on the unattached list of officers. "By order,

"JAMES MCCREA, Lt.-Col., Assist. Adjt. Genl. R.G.M.

"Inspector-General Corbin, Medical Department, R.G.M."

L.R.C.S.—For "port wine stains" do nothing. For nævus on the back, if capillary, apply primarily nitric acid; if venous, either tie, or excise and unite the edges of the wound.

Quis Separabit.—The letter is too long to admit of insertion.

MATERNAL IMPRESSIONS.

To the Editor of THE LANCET.

SIR,—The following case of unconscious maternal impression, or perhaps of mere coincidence, may be worthy of mention.

On the 4th inst. I attended Mrs. S—— in her fifth confinement, and delivered her of a mature male child, who had a harelip, with unequal sides, on the left side, and a double cleft palate. None of her previous children had this deformity, nor was there any history of it in the family. It appears that at the latter end of February or the beginning of March she saw a brother, a soldier home from India on furlough, who had recently been bitten in the upper lip by a dog, and who then had a scar on the left side of the upper lip. At the time of hearing of the accident she was rather upset, though she did not see her brother till after the wound had healed. She had, of course, no idea of its affecting her child, as she could only have been in her first month of pregnancy at the time, and she says she had no thought of the kind subsequently. In most cases of maternal impression which I have referred to I find that the mother was conscious of the impression, and fearful of the result. I have ascertained that there is no doubt about the facts of this case. I am, Sir, yours obediently,

T. GODFREY PARROTT, M.R.C.S.

Cottage Hospital, Bournemouth, Nov. 19th, 1884.

Mr. Senior.—1. The subscription to the New Sydenham Society is one guinea per annum.—2. Apply to a medical bookseller.

MEDICAL HEROES.

To the Editor of THE LANCET.

SIR,—On Feb. 3rd, 1882, died John Topham Gadsby of this place, a M.D., and a Medalist of the London University. His death was caused in precisely the same manner as that of Dr. Rabbeth, and was all the more mournful on account of his leaving a young widow, to whom he had been married only a few months. After performing tracheotomy on a child in the Workhouse Infirmary who was suffering from diphtheria, the tube became blocked, and he at once cleared it with his mouth, contracted the disease, and died. All this duly appeared in the obituary column of THE LANCET at the time; but I am unaware that the slightest notice was taken of the sad event by the members of his University, the profession, or the public.

Now, what I wish to elicit is, the reason why the untimely death of one of these gentlemen should be most justly and generously met by marks of universal condolence and sympathy, while the memory of the other has been treated with cold and heartless neglect. Is it too late to do something, or anything?—Your obedient servant,

Bath House, Mansfield, Nov. 27th, 1884. G. WHITEFIELD SPARKE.

THE TITLE OF BACHELORS OF MEDICINE.

G.—The card looks very well as it is. If others like to accord the higher title to the holders of this goodly degree, well and good; there is no compulsion. But the Bachelor himself shows good taste in using the ordinary title of a gentleman.

"LANCING THE GUMS."

To the Editor of THE LANCET.

SIR,—What would the shade of Marshall Hall say if he could hear the discussion on gum lancing which has lately been recorded in THE LANCET? His dictum was (and I believe still a sound one), it was better to lance a child's gums 199 times unnecessarily than to omit it once if necessary; and I am sure many older practitioners who have followed his teaching can testify that, whether *post* or *propter*, a child almost immediately after its gums are lanced often passes from a distressing state of convulsions, screaming, or feverishness to calm, refreshing sleep, and comparative health and comfort. From the good I have seen apparently follow from lancing the gums I certainly should feel I had not done my duty to a child in convulsions during dentition if I neglected to examine its mouth, and relieve tension by scarifying the gums, cutting off, as Marshall Hall says, the first link in the chain of reflex irritation. I am, Sir, yours faithfully,

Dec. 2nd, 1884. M R.C.S. OF 1845.

TANNERS AND THE CHOLERA.

THE Vienna *Tanners' Gazette* states that an Italian contemporary devoted to the leather trade calls attention to the fact that the tanners in Italy have been spared from the ravages of the cholera epidemic recently rampant in that country, and that in all towns where tanneries existed the plague was of a less virulent character. It has been noticed that streets in which there are tanneries have been altogether spared, whilst other parts of the same town were terribly visited by the cholera.

THE UNITED KINGDOM BENEVOLENT ASSOCIATION.

To the Editor of THE LANCET.

SIR,—At this season of the year all the leading journals liberally open their columns to the appeals of our public charities; and as I feel sure that THE LANCET, the leading journal of the medical profession, will not close its columns to a Christmas appeal on behalf of the widows and daughters of its less fortunate members, I bring under its notice the claims of a society which hitherto has made no special appeal to the medical profession, although it has for many years past been extending to them substantial help. By the report which accompanies this you will observe that the United Kingdom Benevolent Association grants annuities of £20 and £25 to persons of the upper and middle classes in reduced circumstances who are above forty years of age, and who are unable from bodily infirmities to earn their own livelihood, and affords temporary help to candidates in urgent distress. I need hardly say that the applicants for the help of the Society are quite as numerous from the medical profession as from any other class. It has granted annuities of £20 and £25 each to nearly forty widows and daughters of medical men, of whom twenty-nine are now living, and are supported by its bounty at a cost to the Society of nearly £600 a year. There are twenty-three medical candidates awaiting election, among whom are many ladies who are in extreme distress, one of them, the widow of an army surgeon, being paralysed and in great want. Since 1877 the Secretary of the Temporary Relief Fund has made an annual appeal to its subscribers for a Christmas gift for these poor ladies, which each year has been most kindly and liberally responded to.

It has been my privilege to have been associated with this Society from its foundation; and I think the medical profession owes it a debt of gratitude, which I believe they would be glad to have the opportunity of discharging, and which it cannot better repay than by responding liberally to this appeal for a Christmas gift for our distressed candidates.

Particulars of the twenty-three medical cases may be ascertained at the Offices of the Society, 4, Berners-street, Oxford-street, W., by any person who may be willing to assist them in their election or otherwise. Last year our Christmas appeal brought us nearly £800.

I am, Sir, yours truly,

Dec. 9th, 1884. M.D., A MEMBER OF THE COMMITTEE.

Mr. D. S. Donovan, B.A.—We fear there is no chance of our correspondent getting a qualification from any European medical authority. But does he for such work really much require it? People living "hundreds of miles" beyond qualified medical assistance soon discover the aptitudes of missionaries, and will not be slow to recognise any medical faculties they possess, without inquiring closely as to authorisation. Our correspondent might put himself in communication with the Edinburgh Medical Missionary Society.

UNSOUND MEAT.

To the Editor of THE LANCET.

SIR,—I observe in your issue of the 28th ult. an article on the subject of "Unsound Flesh," in which you refer to a recent case where a medical man and a veterinary surgeon gave contradictory evidence. This, Sir, is not the first case of the kind which has occurred, and it is always a matter of grief to me when I see the details of such cases made public, as I am strongly of opinion that the two professions should work shoulder to shoulder in this matter and urge upon the Legislature the necessity of putting it on a proper footing. At the first meeting of the British National Veterinary Medical Association, held last year, in London, I read a paper on this subject, and at the meeting of the same Association, held in July last, in Manchester, I had the pleasure of opening the discussion on the paper written by Professor McCall, and at the close of the discussion I succeeded in getting the unanimous consent of the meeting to a series of propositions on the subject which I was privileged to bring forward. Moreover, in my work on "The Four Bovine Scourges," published in 1879, I dealt fully with the matter of meat inspection, as I have also done on a number of public occasions. The matter as it at present stands is in a very unsatisfactory, and I may say dangerous position, as no definite or authoritative rules are laid down for the guidance of inspectors of meat, and I hope the time is not far distant when a joint commission of medical men and veterinary surgeons will be appointed to consider the subject with a view to the inauguration of legislative action by the Government. I, for one, shall be happy to assist in bringing about such a desirable consummation, and I trust your powerful aid will not be wanting.

I am, Sir, your obedient servant,

THOMAS WALLEY, Principal.

Royal Veterinary College, Edinburgh, President of the R.C.V.S.
Dec. 9th, 1884.

COCA PASTILS.

WE have received from Mr. Martindale, New Cavendish-street, a sample of pastils prepared from erythroxylon coca. They are intended for the temporary relief of hunger, thirst, fatigue, exhaustion, distaste for food, or nervous depression and weak digestion. One or two of the lozenges are to be allowed to dissolve slowly in the mouth every two or three hours.

THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

To the Editor of THE LANCET.

SIR,—The time is approaching when it will be necessary to consider how to utilise fully the opportunities afforded by our new building for the study and treatment of nervous disorders upon a scale not hitherto attempted in this or any other country. The Board of Management are naturally anxious that the new hospital shall not prove an additica to those institutions whose ward space is in excess of their means to make use of it, and they desire that with as little delay as may be a large proportion of the beds—all, if possible—shall be put at the service of the staff. The institution has always been "National" in something more than its name. Even with the limited accommodation of the old buildings it has dealt with patients from nearly a thousand cities, towns, and villages of the kingdom. Many of these places, although rich and important, have contributed nothing towards the outlay incurred; and experience shows that when it is a question of obtaining funds not for a special and conspicuous purpose, but year by year to be expended upon maintenance, a national institution is prejudiced by its want of locality. We now seek to minimise this disadvantage, and, if possible, to overcome it. A hospital whose wards contain at one time patients from a dozen different counties and fifty different towns is really a group of little local hospitals collected under one roof, and it appears eminently reasonable to invite those districts which send patients to assist towards their cost. A proposal which has received the sanction of the Board of Management is calculated to bring about some such co-operation, and greatly to increase the value of the new hospital. It contemplates the allotment of beds to certain districts, either for a specified number of years upon a contribution to the capital funds, or year by year upon an annual subscription. The contributions suggested are £500 for the allotment of a bed for fourteen years, or an annual donation of fifty guineas. It is needless to say that these figures represent a much less sum than the actual cost of the bed, while, as the only object in view is to increase the hospital's power of usefulness, the accommodation for patients from contributing districts will not be limited to the reserved beds, but applicants will possess the same chance of admission as heretofore to any bed which may be vacant. In these days of hospital penury the idea may be commended to any metropolitan institution in similar case, though none other stands so isolated as this, and to local philanthropists desirous to do their poor neighbours a service in which all the world may share. Of course, a patient will be admitted only in conformity with rules. He must be suitable for gratuitous treatment, and his fitness medically considered will be judged of by the physicians of the hospital, either upon personal examination, or upon information supplied in regular form by a local practitioner. If the beds were in some way affiliated to the provincial institution, possibly local interest, both philanthropic and professional, would be stimulated, and valuable means might be obtained for the diffusion of knowledge in regard to diseases of the nervous system. Finally, were the idea generally adopted, we need no longer fear that for lack of means our new wards will fail to be fully utilised, to the detriment of the sick poor and the no less certain loss to science and humanity at large.—I am, Sir, your faithful servant,

B. BURFORD RAWLINGS, Secretary.

National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-sq., Bloomsbury, Nov. 24th, 1884.

"THE SEVERE, OR SO-CALLED 'UNCONTROLLABLE,' VOMITING IN PREGNANCY."

To the Editor of THE LANCET.

SIR,—The paper of Dr. Grally Hewitt on the above subject, read before the Obstetrical Society and published in your last issue, suggests to the mind of a once busy practitioner a remedial means of which the late Dr. Marion Sims was, I believe, the author. This consists in applying to the cervix uteri once a day a solution of the nitrate of silver, of the strength of from twenty to sixty grains to the ounce, lengthening the intervals as relief is obtained. Cases will have occurred to many wherein no deviation from health could be diagnosed, and where the newly active organ might only affect the stomach through its "reflexes." In this class, as well as in those wherein a more tangible cause was obvious, the course mentioned has many times quickly and completely relieved my patients when artificial abortion appeared imminently necessary, and, stranger still, the relief was generally permanent, the operations rarely requiring repetition. Certainly, many anxious practitioners will find room for such a simple means before resorting to the severer operation. My own chosen method was to employ a solution of silver in equal parts of pure sweet spirits of nitre (fresh) and distilled water, painting the whole visible cervix through a speculum, and leaving as a dressing a pledget of absorbent cotton soaked (and then squeezed) in glycerine. I have rarely been obliged to make a fourth application. I am, Sir, yours faithfully,

London, Nov. 22nd, 1884. M.D. (U.S.A.)

Digitized by Google

IRREGULAR PRACTICE IN CAPE COLONY.

A VERY sensible article appears in *Port Elizabeth Telegraph and Eastern Province Standard* on the harm done by allowing irregular practitioners to carry on practice in remote districts, and advocating the publication of simple instructions by Government for use as first aid in districts where medical men are few. In thinly populated communities doctors are sometimes ten or twenty, or more, miles away from the inhabitants, and a sound set of instructions would be infinitely preferable to a travelling pretender to the art of physic.

ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—On reading the discussion which has recently taken place at the Medical Society of London on the above subject I was somewhat surprised to find that no mention was made of the hypodermic injection of ether in the case of the circulation or respiration failing; for I have always found this to prove a most speedy and effectual measure in resuscitating the patient when all other methods have failed. The sensation caused by the injection of ether has frequently been described to me by patients as being of a peculiar tingling sensation over the whole body, from the tips of the fingers to the extremities of the toes, thus showing its speedy stimulating action. Perhaps the great drawback to the hypodermic injection is that a suitable syringe is not always at hand the moment it is required. As a *dernier ressort*, however, I am strongly in favour of applying almost scalding water, by means of a flannel, to the forehead. May I mention, by way of conclusion, that I have invariably found the "hot water" application to be invaluable in various cases of syncope, and above all for the most speedy restoration or establishment of the circulation of newly born infants.

I am, Sir, yours truly,

Baron's Court, S.W., Nov. 26th, 1884. R. FITZROY BENHAM.

CYCLING: "THE SWING FRAME."

To the Editor of THE LANCET.

SIR,—From the correspondence I have noticed regarding the liability of cycling to injure the rider owing to the pressure of the saddle, I quite agree with the reply of Mr. Battams as to the very remote chance there is of injury. I think the tricyclist is more subject to this liability than the bicyclist; for it is a well-known fact that the rider is very apt to sit forward on the peak of the saddle when riding a hill. Being a cyclist myself, and finding it of great assistance, I wish to mention an invention which entirely prevents any possibility of injury, and in this hilly locality it is especially useful. I refer to the "swing frame," which by its action depresses the peak of the saddle on a hill, and brings the rider forward over his work. As I can thoroughly recommend its action, and feel sure it prevents what at times may be an injury, I bring it to the notice of your readers. The inventor, Mr. Warner Jones, of 14, Bury-place, Bloomsbury, London, will, I am sure, be happy to explain its action to anyone who writes for information.

I am, Sir, yours faithfully,

Exeter, Nov. 18th, 1884. EDWARD A. BRASK, L.R.C.P.Lond.

"PARTIAL INQUESTS."

To the Editor of THE LANCET.

SIR,—Referring to your article under the above heading in your issue of Nov. 29th, I should like to bring before your notice, and that of your readers, the following case.

On Nov. 27th Charles Henry D——, aged seventy, was found suspended by a rope round the neck. When found the body was warm. No medical man was sent for. A coroner's inquest was held without medical evidence, when a verdict was returned that deceased committed suicide whilst in an unsound state of mind. The body being warm, is it not possible that under proper treatment death might not have ensued? Again, is there any proof that death was not the result of poisoning, and that the deceased was subsequently suspended? I could mention other cases in point; but the above case is in itself sufficiently striking, and shows that "our coroners fail to carry out the provisions of the law."—I am, Sir, yours truly,

WILFRED HOWARD, M.R.C.S.Eng., L.R.C.P.Ed.

Littleport, Isle of Ely, Nov. 30th, 1884.

"STRANGE MIGRATION OF A NEEDLE."

To the Editor of THE LANCET.

SIR,—Dr. Campbell Black's case is replete with interest. It is unusual at the first to feel the needle-*point*, but having done so, and after vain attempts at extraction, he seems to have been well advised in cautioning the patient against following his example lest still "greater injury" might result. After eleven months' journeying through the tissues at the rate of about six inches and a half per mensem, the needle issues at last with out help from the faculty, and lo, the point is quite clear! The point that must be clear to everyone but Dr. Black and his lady patient is this, that having entered the *right* thumb, the needle leisurely travelled up one digit and doubled down the next, and that Dr. Black and the lady were left pursuing in unconscious companionship a headlong chase in the direction in which the doctor had felt the needle-point.

I think David Hume would thus have explained away this latest of miracles. I am, Sir, yours obediently,

London, Nov. 10th, 1884. W. MCLAURIN.

PARIS LUNATIC ASYLUMS.

THE Prefect of Paris Police states in his annual report that the total number of lunatics in the asylums belonging to the French capital was 8907 at the beginning of the year, but that it is now over 9500, this large increase being attributed more to the anxiety of relatives to avail themselves of the better accommodation now provided in French asylums than to an actual development of insanity. There is, however, a certain increase of insanity as well, and this is doubtless due to the spread of drunkenness among men, who now form 55 per cent. of the insane, whereas a quarter of a century ago they were only 45 per cent. There are four special asylums for the insane within and outside the walls of Paris. The total estimated expenditure for the current year is £232,000, or £28,000 more than last year. This expenditure is borne in part by the municipality, and in part by the parishes of which the patients are natives, while the Government pays for all insane soldiers, sailors, and prisoners.

ALLEGED DEATH FROM VACCINATION.

To the Editor of THE LANCET.

SIR,—A short time ago you alluded to an inquest in which I was concerned, where the jury returned a verdict of "Death from convulsions arising from vaccination," though the death was undoubtedly due to suffocation.

There are a few lessons to be deduced from the case which, with your permission, I will lay before my professional brethren, for their guidance, should they be placed in the same circumstances as I was.

1. It may be taken as a fact that in future in any case of sudden death in an infant who has been recently vaccinated, an attempt will be made to "hook on" the death to vaccination, if the circumstances can possibly be made to fit in with such a theory. If therefore any medical man be called to such a case, I would strongly advise him to ascertain all the facts as to lymph supply, and the state of the child's health when vaccinated and shortly before its death; and, moreover, to get at these facts directly after the death; for if any sympathising anti-vaccination agent interviews the mother, the facts (?) will be told in a very different manner to what they are, at the time the case first comes under notice, and before any leading questions have been put or suggestions made.

2. If the question be brought up at an inquest, and an adverse verdict proposed, the medical man must refuse to accept it, without a post-mortem be made, and must ask the coroner to adjourn the inquest for that purpose. In my case the jury wished to bring in a verdict of "Death from blood-poisoning, arising from vaccination," though not one particle of evidence had been adduced to prove it, and the subsequent post-mortem disproved it.

3. Let the coroner appoint the gentleman who is to make the post-mortem, and not allow the jury to do so; at the same time the medical man must insist on being present, and have with him, if he wish, some independent skilled witness—some pathologist of known repute for example.

4. The medical man must be on his guard about another matter—viz., that if the case be one of convulsions, an attempt will be made to show that these were due to the irritation of the arm. In my case there was no evidence to show that convulsions existed, and four of us gave a positive opinion to that effect.

I am, Sir, your obedient servant,

The Oaklands, Upper Clapton, Nov. 29th, 1884. CHAS. T. AVELING.

THE DUCT OF GARTNER.

To the Editor of THE LANCET.

SIR,—I have recently observed that in many English works the name of the anatomist who first described the more or less persistent traces of the efferent duct of the Wolffian body, as seen in adult female mammals, is constantly spelt "Gaertner." That anatomist was not a German, but a Dane, and in Danish the word, whether a proper name or signifying "gardener," is spelt "gartner." The work which he wrote on the above subject is entitled, "Anatomisk Beskrivelse over et ved nogle Dyr-Arters Uterus undersögt glandulost Organ." It was published in Copenhagen in 1822. I am, Sir, yours truly,

Seymour-street, W., Nov., 1884. ALBAN DOMAN.

VICTORIA DENTAL HOSPITAL, MANCHESTER.

THE dental specialists are still given to advertise very much. A handbill has reached us advertising the above hospital, with all the surgeon's names on the back. This is not a commendable or professional procedure.

TO AMUSE THE CHILDREN.

To the Editor of THE LANCET.

SIR,—Would any of your readers kindly lend a magic lantern for one evening to amuse some country school children. It would be to them much like the visit to Drury-lane is to the London arabs. I would, of course, pay all expense of carriage, &c., and be responsible for any injury that might happen to the lantern. It would have to burn oil.

I am, Sir, yours obediently,

South Hayling, Hants. PERCY POPE, M.R.C.S.

ERRATUM.—The age of the boy referred to in Mr. Douglas's letter on "Supposed Cancer of the Rectum," published in our issue of Nov. 29th, p. 983, was fourteen years, not nineteen.

Medical Diary for the ensuing Week.

Monday, December 15.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
MEDICAL SOCIETY OF LONDON.—Sir Andrew Clark, Bart.: A Case of Relapsing Pneumonia in an Aged Man, with Some Observations on the Nature of the Disease.

Tuesday, December 16.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M., and on Fridays at 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
PATHOLOGICAL SOCIETY OF LONDON.—Dr. Wilks: Intestinal Obstruction produced by Gall-stones.—Dr. Carrington: Thyroid from a case of Exophthalmic Goitre.—Mr. Rose and Dr. Sainsbury: Gunshot Injury of the Brain.—Dr. Hale White: The Sympathetic System, from Four Cases of Diabetes; Patent Ductus Arteriosus (card): Abnormality of Lung.—Mr. Godlee: Fracture of Skull in an Infant followed by the Effusion of Serous Fluid.—Mr. Lane: Fracture of First Rib.—Dr. Norman Moore: Hæmorrhage into Substance of Liver.—Mr. Pepper: A Case of Malignant Disease of the Spermatic Cord.—Mr. D'Arcy Power (for Dr. Mackinder): A Pouched or Duplicate Bladder (card).—Mr. G. R. Turner: A Drawing of Congenital Deformity of the Perineum (card).

Wednesday, December 17.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays, at 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.—Skin Department: 9.30 A.M., on Tuesdays and Fridays.
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations 2½ P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Thursday, December 18.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.
NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

Friday, December 19.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.
SOCIETY OF MEDICAL OFFICERS OF HEALTH.—7.30 P.M. Mr. Henry P. Armstrong: The Status of the Medical Officer of Health as a Criterion of Sanitary Progress.

Saturday, December 20.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year..... £1 12 6 | Six Months..... £0 16 8
TO CHINA AND INDIA..... One Year 1 16 10
TO THE COLONIES AND UNITED STATES .. Ditto 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

Remarks ON THE GENERAL PERFORMANCE AND TREATMENT OF AMPUTATIONS.

By JAS. WHITSON, M.D., F.F.P.S.G., F.R.M.S.,
ASSISTANT-SURGEON, GLASGOW ROYAL INFIRMARY.

AMPUTATIONS have always been of frequent occurrence in large industrial centres, though since the introduction of the antiseptic system the necessity for their performance has considerably diminished. The loss of a limb, whether partial or amounting to complete dismemberment, is a serious privation for any individual to encounter; and under these circumstances it is the duty of the surgeon, in effecting its removal, to adopt measures which will yield the greatest prospect of recovery and secure as much future comfort as possible. The practices which were in vogue fifteen or twenty years years ago were unsatisfactory on many grounds, and, as a natural consequence, the death-rate was high, convalescence among those who survived was only reached after long and tedious intervals, while the trouble and anxiety falling upon all in charge were incalculable. Suppuration was the ordinary concomitant of wounded surfaces, and its effects upon the patient were depressing in the extreme. Neither need this be wondered at when we remember that pus is a product of inflammation derived mainly from the white corpuscles of the blood, and is, on account of their withdrawal from the circulation, not only a disturber of nutrition, but a heavy drain upon the recuperative powers of the patient. Nor was this all, for when decomposition set in, the receptivity possessed by the tissues led to the absorption of poisonous material, and was a fertile source of the numerous epidemics of pyæmia and hospital gangrene which were so disastrous in their effects when they extended through the wards of a large hospital. Happily, in the midst of these complications, the antiseptic system came to our aid. Its chief end was the prevention of decomposition, and the results subsequently attained through its instrumentality have clearly proved the truth of the theory first propounded by Lemaire, that wound products become altered under the influence of contaminated air, and give birth to a series of phenomena due to one and the same cause—fermentation. The views held by this distinguished Frenchman, and afterwards successfully worked out by Lister, were almost universally received with doubt and distrust, while many eminent members of the profession openly ridiculed and condemned them, without even waiting to test their stability or verify by actual observation the correctness of the data which had been advanced regarding them. The antiseptic system has, however, stood the test of time—the most trying of all tests,—and the verdict which must now be given is that its adoption has proved an incomparable boon to surgery, not only on account of the improved forms of treatment and subsequent immunity from bad effects it has given rise to, but for the many departures from the beaten path now practised with safety, and which adherence to its principles warrants.

Performance of Amputations.

Amputation, though essentially a radical measure, is at the same time a conservative act, and its performance may be required either in consequence of injury or for the removal of disease. Certain axioms have long since been laid down as necessary for the successful conduct of this class of operations, and many of the dicta of the older writers are, with certain modifications, still upheld and acted upon by the leading surgeons of the present day. Thus, while recognising the propriety of taking away an affected part in its entirety, we make it a rule not to go nearer the trunk than is necessary, and it is a fundamental maxim that skin must cover muscle just as muscle ought to envelop bone. Before proceeding to operate it is our duty to see that the parts which are about to be subjected to surgical interference are thoroughly clean, because impurities which are allowed to remain may vitiate the result; and in such cases failure is not unlikely to be ascribed to some element entirely foreign to the true cause or a mere accident in its production. If these precautions require to be taken on behalf of the patient, similar vigilance is equally necessary on the part of the surgeon and his assistants. Their hands must be freed of all matter capable of becoming a focus for the spread of decomposition, while every instrument ought to be in faultless order. Nothing more plainly bespeaks slovenly arrangements on the part of, or is so derogatory to the reputation of, the surgeon as badly kept or dirty instruments; and few things are more likely to react prejudicially than the apathy which permits such a state of matters to exist.

It is well to bear in mind the fact that an amputation should never be attempted without efficient help, and the adoption of the divisional system greatly contributes to its more perfect performance; each man being assigned a post, and if possible being practised in, and therefore conversant with, the particular part allotted to him. If, for example, we are called upon to remove a leg, one assistant should be entrusted with the holding of the thigh, a second ought to grasp the foot, and a third can attend to the retraction of the flaps. The instruments are best placed under the care of one person, and the sponges[1] under that of another; while nurses ought clearly to understand the position they are to occupy, and the nature of the service expected from them. In this way work is more expeditiously performed, there is a total absence of confusion, and time as well as labour are utilised to the utmost advantage.

In all amputations it is of paramount importance to reduce the loss of blood to a minimum. The old mode of controlling the circulation in a limb used to be for an assistant to grasp the parts above the seat of operation and compress the main artery at its most convenient point; but though the chief vessel may be commanded by this means, its branches are unlikely to be so, and the parts below are not rendered exsanguineous. A further drawback to such a mode of procedure is that the hands of the person who is entrusted with this duty are apt to become cramped from the continuous strain placed upon them, and if the fingers are relaxed a considerable quantity of blood escapes, which adds to the difficulty of ligaturing the blood-vessels, and at the same time weakens the patient. The tourniquet of Petit was an advance upon this; but as the compression exercised by the screw and strap is confined to a limited area, its employment cannot be well borne for any length of time. The elastic rod with the catch of Foulis is even worse than the means just mentioned, and if stretched tightly round a limb may give rise to sloughing of the tissues in its neighbourhood.[2] With both these agents, unless special precautions are taken to the contrary, a large quantity of blood is imprisoned below the seat of amputation, and is thus wasted.[3] Both are also liable to produce a temporary paralysis of the vaso-motor nerves in the locality, and until the atony consequent upon this procedure passes off, the capillaries and smaller arterial twigs remain dilated. Their power of contractility is not regained for some time, and so long as such a state of matters exists oozing will continue to go on. Fortunately, however, we have in the elastic bandage a means of attaining our end which is in great measure free from the drawbacks just alluded to. The amount of pressure exercised by it gives rise to no uneasiness,[4] and its action, while cumulative in principle, is twofold in character—emptying the parts of blood and controlling the circulation. Its application should be commenced at the distal extremity of the limb which is to be operated on,[5] and carried as far upwards as may be deemed advisable. The webbing is then unrolled from its lowest end, and when uncoiled to a sufficient extent is finally wound round its uppermost folds and made fast by a safety pin; or, if more convenient, a second bandage can be affixed above the first one, the latter being removed as soon as the former is secured. When we have to

[1] Sponges ought to be perfectly clean and freed from every particle of sand or septic material. During an operation sponges after being used had better be thoroughly washed, in order to rid them of blood, and they should be wrung out of the carbolised solution before being handed to the surgeon.

[2] An instance of this is referred to in the Glasgow Medical Journal for January, 1883, page 9, and a short experience of the rod on one's own person will soon convince the most sceptical in regard to the truth of the statement. Such a complication is more likely to occur in the arm than in the thigh, the former not being so well clothed with soft parts as the latter.

[3] All who have witnessed the performance of amputations when these modes were prevalent must recollect the gush of venous blood imprisoned below the seat of operation which succeeded the cutting of the vessels.

[4] This is accounted for by the webbing being spread over a large surface.

[5] Prior to the application of the bandage the limb should be elevated.

Digitized by Google

deal with a limb which is the seat of malignant disease,[6] or with one which contains a large collection of purulent fluid, it is inadvisable to adopt this method of rendering the parts exsanguineous because of the forcing of diseased material into the tissues.[7] In such cases the difficulty may be overcome by raising the limb to a vertical position for four or five minutes, and then putting on the bandage above the site selected for operation. Elevation[8] under such circumstances no doubt contributes towards the emptying of the bloodvessels, but the chief factor in producing ischæmia is a nervous one, the stimulus which is given to the vaso-motor system by the diminution of pressure, caused by the action of gravity on the contained blood, acting on the arteries and inducing a reflex contraction of their parietes.

The Cutting of the Flaps.

The shaping of the flaps now claims our consideration, and amongst the different styles of fashioning these we may first mention the circular, which has no lack of advocates, and is much practised in America. The method recommended by Teale is one which is frequently followed, and in many ways it is an excellent mode of operating. The flaps when accurately measured come nicely together, there is a natural drainage, and the cicatrix lies out of harm's way; but as the anterior flap requires to be one-half the circumference of the limb, a needless sacrifice is entailed, and we thus go nearer the trunk than is really necessary. Lister[9] in some degree meets this difficulty by making the anterior flap equal to two-thirds of the diameter of the limb, and the posterior flap half the length of the anterior. At the present time many surgeons seem to be in favour of flaps of nearly equal length, though circumstances frequently alter cases and render adherence to any fixed rule a matter of impossibility. It often happens, for example, in cases of injury that the tissues on the front of a limb are severely crushed, while those on the posterior aspect remain comparatively sound. Under these circumstances we are compelled to select a long posterior flap with a short anterior one, because the latter, from its bruised condition, will, if retained, almost certainly slough. In whatever way we proceed we ought always to secure abundant covering for the end of the bone in order to ensure freedom from tension; and if the drainage be good and other conditions favourable, any special formation of flaps is a matter of minor importance.

We will now suppose the various preliminaries have been attended to, the parts at the seat of election cleaned[10] and shaved, the limb emptied of blood and firmly held, and that the operator is ready to proceed in the execution of his task. The shape and length of the flaps having been decided on, the first incisions ought to be made with a free sawing motion of the knife, the point of the blade being made to penetrate through the entire thickness of the skin.[11] A skilful hand should retract the flaps as these are gradually dissected back, care being taken by the surgeon to include the whole of the cellular tissue in order that the vascularity of the tela adiposa may not be encroached upon, and keep them out of harm's way when the operator is cutting the muscles and sawing through the bones. During the latter process the distal portion of the limb ought not to be depressed or elevated beyond a certain extent. Should we fall into the first of these errors, the edges of the bone are apt to be splintered; and if the second be not avoided, the instrument is liable to become locked between the osseous surfaces. Any little projections which happen to remain can be filed down with the rasp.[12]

Ligaturing of the Bloodvessels.

When the separation of the limb from the trunk has been accomplished, our next duty is to see to the occlusion of the bloodvessels, and it is of the first importance to close as many of their divided ends as we possibly can. Should this precaution not be attended to a greater or lesser amount of oozing will ensue, and if the material which has exuded does not obtain a ready exit tension speedily follows. The securing of the arteries will be greatly facilitated by having a number of pairs of catch forceps ready to affix to their various mouths. After these are applied the different points can then be ligatured, and the process repeated as often as is necessary until the whole area of the stump is gone over.[13] One great advantage of the elastic bandage is that from the artificial ischæmia which it produces the empty channels of the larger arteries can be seen and tied with ease and deliberation, and without loss of blood to the patient. Silk was at one time almost universally employed in the ligation of arteries, and surgeons were in the habit of leaving the ends long in order that the whole thread might be pulled away after the lapse of a certain time. To some extent strands of this material also acted as drains, but the porosity of their fibres and consequent liability to be infiltrated with inflammatory products proved sources of disturbance. Chromicised catgut is to be preferred for this purpose, because while equally efficient its presence in a wound gives rise to no irritation, and being cut short is in the majority of cases ultimately absorbed. In ligaturing bloodvessels care should be taken to isolate their parietes, in order that adjoining structures may not be included. Nerve trunks are best cut short, as their presence in a wound is undesirable, and may give rise to future complications.

(To be concluded.)

[6] More especially those of the soft type.

[7] The mode just alluded to would also have been undesirable in a large diffuse aneurysm of the femoral artery which I happened to see not long since, and where an immense quantity of clotted blood was turned out previous to tying both ends of the vessel.

[8] See Holmes' Surgery (third edition), vol. iii., page 708. See also an Address on the Influence of Position upon Local Circulation, by Joseph Lister, F.R.S., Brit. Med. Jour., June 21st, 1879, page 923.

[9] Holmes' Surgery (third edition) vol. iii., page 706.

[10] It sometimes happens that a limb is besmeared with grease, and in such cases a little spirit of turpentine will be found one of the best agents for removing it. Under ordinary circumstances soap and water are sufficient for cleansing the parts. There are many surgeons who use ether for this purpose.

[11] An excess of covering should always be preferred to a deficiency, because any redundancy soon contracts to its normal limits.

[12] It leaves a smoother surface than the bone forceps, which are usually employed for this purpose. An excellent style of rasp is made by Thamm, of Berlin.

[13] This will be found to be a better plan than the one which used to prevail of seizing any vessel indiscriminately, ligaturing it, and proceeding towards it in the same fashion.

ABSTRACT OF REMARKS ON A CASE OF

RELAPSING OR INTERMITTENT PNEUMONIA OCCURRING IN AN AGED MAN.

BY SIR ANDREW CLARK, BART., M.D.,
PHYSICIAN TO THE LONDON HOSPITAL.

ON the 25th March, 1884, the patient was first seen, and had for five days suffered from disordered digestion and malaise, with aching pains and feverishness. He was a gentleman aged eighty-two, of vivacious appearance, light and spare frame, and of active habits. In 1877 he had had an attack of pneumonia. There was a history of his having caught cold, and when first seen the countenance was pinched; the eyes were dull; the face yellowish, the tongue loaded, the appetite gone; there was thirst; the abdomen was full; the urine high coloured, free from albumen, but loaded with urates. The breath sounds were feeble at the posterior base of the right lung. The pulse beat 86 times per minute; the smaller arteries were exceptionally soft, and otherwise sound; the skin was hot; there was a dull headache with languor. A fluid diet was ordered, with a saline draught, and a colocynth and blue pill was given at 10 P.M. On the 26th a rigor set in; the temperature rose to 103°; the pulse was 94 per minute. The breath sounds were very feeble at the right base. Poultices were ordered; salines and the pill were repeated, and an enema was prescribed. On the 27th another severe rigor came on; the general condition remained unaltered. Now there was feeble bronchial breathing with increased vocal resonance. On the 28th another rigor set in; the mouth and tongue became dry; the thirst was increased. The bowels had been relieved. The temperature registered 104°. There was dulness over the posterior base of the right lung; the respiration numbered 24 per minute. There had been no cough. Half an ounce of brandy twice or thrice a day was prescribed with small doses of quinine. On the morning of the 29th the report showed a restless night, but no fresh rigor had occurred. The temperature was 100°, the pulse 80, the respiration 28. The patient felt much better, and had taken food well. Dulness with increased vocal fremitus, and tubular breathing with bronchophony, were made out at the right posterior base. There was no pain and no distress of breathing. On the 30th there was general improvement. On the 31st a fresh

Digitized by Google

rigor was observed, and the patient got rapidly ill again; the temperature was 103°, the pulse 110, the respiration 32. The tongue was loaded and dry, and there were signs of fresh consolidation in the middle of the right back. The lower part of the right lung remained much the same as before. An alkaline saline was ordered every four hours, with brandy, quinine, and poultices. On April 2nd the patient said he was well, and the skin was moist. There were moist crepitations over the right lower back. Within four hours of the time at which these notes were made the pulse and temperature had risen rapidly, and there were signs of renewed illness. Cough set in for the first time; the face became bluish. The signs of a third strip of consolidation were detected higher up in the right back. The brandy was increased in quantity, and ammonia was added to the medicine; hot bottles were applied to the extremities. Again, on April 3rd, the patient was better; the temperature had fallen to 96°; the pulse was 80, but very weak and small. In the evening the temperature was 103°, and the consolidation had extended upwards. The notes of April 5th speak of improvement, but towards the evening the patient suddenly chilled, and all the symptoms grew bad again. The next morning the temperature was 97°, but at noon a sudden severe and prolonged rigor occurred. Strong soup and other stimulants were persevered with. There was now dulness on percussion at the base of the left lung; the skin was cold at the extremities, though everywhere dry. Another rigor occurred on April 7th, and afterwards on each day at half-past twelve there was a rigor till the 11th and 12th, when none occurred. At midday on the 13th another rigor supervened, and the patient was much exhausted; there were large crepitations to be heard at the base of the left lung. On the 14th he passed a fair night, and the temperature was 96°; there was an occasional cough and a slight amount of viscid, unstained mucoid expectoration. At midday the worst state of the patient was reached; the skin became dusky, dry, and hard, with a severe rigor; the pulse was small, weak, and irregular, and he had the aspect of one suffering from cholera. He remained in this state about four hours, and then began to recover at about five P.M. The urine contained a little albumen; there was no cough and no expectoration. The pulse was 116, compressible and irregular. There were the signs of consolidation of the upper part of the left lung. On the 15th he improved till the evening, and on the 16th he was greatly better. Later on the physical signs were clearing up, and the temperature was 98° in the evenings. The diet was changed to semi-fluid articles, and claret was allowed. On the 6th May the patient was fully convalescent, and complete recovery soon followed. The patient had passed through as many as nine or ten severe rigors with six pneumonic consolidations and seven weeks' illness.

In his remarks on the case Sir Andrew Clark spoke of the remarkable character, assemblage, and progression of the symptoms, and of the age of the patient, making the case one of great rarity in the annals of medicine. The nature of pneumonia, whether it were a local disease or a fever with a local manifestation, was touched upon. If pneumonia be really an inflammation or not was a question which had concerned him for many years. In his work on pneumonia Dr. Sturges considered that the phenomena of inflammation were conspicuously exhibited in pneumonia, and that the anatomical and histological phenomena were fully satisfied. Further, he not only considered pneumonia to be inflammatory, but regarded it as the pattern and model of all inflammations. Sir Andrew had contested these views at the Royal College of Physicians as long ago as 1866. In a consolidated pneumonic lung we might histologically investigate the solid exudation in the alveoli, the relations of the exudation to the alveolar wall and the condition of the alveolar wall itself. In investigating these three conditions he failed everywhere to find any signs of cell proliferation, and there were nothing but the signs of regressive change. The number of red discs extravasated in acute pneumonia equals or exceeds the number of leucocytes; the blood-discs were undergoing changes in the fibroid network just as in blood-clots. In the alveolar septa there was no evidence of any change with the exception of occlusion of some of the bloodvessels. Dr. Johnson had shown that in acute nephritis the vessels were not occluded but much enlarged. The absence of signs of active cell proliferation made one ask whether the alveolar tissues might not be incapable of any other manifestation of the inflammatory process. But the facts observed after traumatic influences, in connexion with tubercles and as a result of inhaled irritant particles, or from the spread of inflammatory processes from the pericardium or pleura, negatived such a notion. These considerations made him believe that the consolidation of pneumonia, though it might be an abortive inflammation, was much more like an active congestion in which capillary extravasation took place before the inflammation could be continued to its classical completion.

With regard to the principles which guided him in treatment there were possibly none, and medicine might be said to be the most unprincipled of arts, and that every case was a law unto itself. He had given, first, attention to the man, and next to the malady. The food was given in relays, not too liberally nor too frequently. He endeavoured to maintain the vigour of the circulation, and by other measures, such as warm sponging, the maintenance of gentle evacuations, the absence of noise or fussiness, with light and fresh air to keep the organism in the best possible state for recovery.

THE TRUE VALUE OF PICRIC ACID AS A TEST FOR ALBUMEN AND SUGAR IN THE URINE.

BY GEORGE JOHNSON, M.D., F.R.S.,
PROFESSOR OF CLINICAL MEDICINE, SENIOR PHYSICIAN TO KING'S COLLEGE HOSPITAL.

RATHER more than two years ago the discussion on the use of picric acid as a test was commenced in the pages of THE LANCET. The object of the present communication is to summarise the result of that discussion. And first, I beg sincerely to thank those who frankly stated what they believed to be objections to the test, for the result has been that its true value has been more speedily and firmly established than it could have been if it had been left unnoticed and uncriticised. The objections to its use as an albumen test have been the following:—

1. It was said that it gives with peptones a precipitate not distinguishable from albumen. It is a fact that it gives with peptones a precipitate at first sight like albumen, but I was the first to show that the peptonous precipitate, unlike the albuminous, is completely redissolved by heat much below the boiling-point of water. Now, this power of precipitating peptones when mixed, even in very minute quantities, with urine constitutes one of the chief uses of picric acid as a test. I have always insisted on the importance of applying a boiling temperature to every urine in which picric acid throws down a precipitate. Such a precipitate, if composed of albumen, is always made more dense and voluminous by heat; while, on the contrary, a peptonous precipitate entirely disappears, and one of mixed peptones and albumen is lessened by heat. The result of this extremely simple and accurate mode of testing for peptones has been that I have found them in only two out of several hundred specimens of urine. The often repeated statement that peptonuria is of frequent occurrence is, I believe, a result of trusting to Fehling's solution as a test for peptones. That agent gives with other substances, certainly with albumen, a red colour which is not distinguishable from that which results from a peptonous mixture. Nothing can be easier than to separate peptones from albumen if they should be combined in the same urine. This may be done in two ways:—1st. The albumen having been coagulated by heat, the peptones, which are not affected by heat, may be separated by filtration. 2nd. The mixed peptones and albumen having been precipitated by picric acid, the peptones are redissolved by boiling, and then separated by pouring the boiling liquid on a previously heated filter. The coagulated albumen will be left on the filter, while the picrate of peptones in the filtrate will be re-precipitated on cooling. I claim, then, for picric acid that it is at once the most delicate and trustworthy known test for peptones in the urine.

2. It has been truly stated that picric acid gives with the *vegetable alkaloids*, such as those of cinchona, a precipitate like albumen—like it, that is, at first sight, but unlike it in being completely redissolved below the boiling-point of water, and therefore not to be mistaken for albumen by those who follow the rule of applying heat to every precipitate or opalescence caused by picric acid. It is only when

Digitized by Google

large doses of the vegetable alkaloids are introduced into the stomach, such as a five-grain dose of quinine, that enough escapes through the kidneys to give a precipitate with picric acid. Cases may occur, such as those of poisoning by opium or its alkaloid, in which picric acid as a urinary test for morphia might be of practical value.

3. It is a fact that picric acid, like nitric or any other acid, when added to urine, sometimes, though rarely, causes a turbidity from precipitated urates; this precipitate, however, unlike albumen, is at once and completely redissolved by heat.

4. It has been repeatedly and confidently asserted that picric acid precipitates *mucin*, but this statement can easily be proved to be erroneous. In fact, picric acid is the only common test for albumen, except heat, which has no apparent effect on mucin. All normal urines contain, partly in solution, and therefore not separable by filtration, and partly suspended, a substance which it is the custom to call mucin, and which is known to be coagulable by acetic and citric and by the dilute mineral acids. A few drops of acetic or solution of citric acid added to most, if not all, normal urines render them, in the course of a minute or two, slightly but decidedly hazy or opalescent when viewed against a dark background, which is essential in all cases of delicate testing. This haziness forms slowly, and is in no degree increased or diminished by boiling. So with nitric acid, as Dr. Wm. Roberts correctly and clearly states in the recently published *Medical Chronicle*, p. 2, "when a urine, containing both albumen and *mucin* is tested by the *contact method* with nitric acid, the albumen is thrown down just above the line of junction of the two fluids, while the mucin is brought into view towards the upper part of the column of urine, where it gradually forms a diffused haze, quite distinct from the opalescent zone at the line of junction." This haze is due to the action of the nitric acid, diluted by diffusion through the urine, upon the mucin. Now, when a saturated solution of picric acid is added in about an equal volume to a normal urine, the mixture remains quite transparent, except in the rare case of turbidity resulting from precipitated urates, which heat would at once remove. But the addition of acetic or citric acid to the mixture of picric acid and urine will gradually cause a considerable haziness, as will the addition of picric acid solution to urine with which acetic acid has been previously mixed. In this experiment the picric acid renders more apparent the haziness which results, not from the picric, but from the action of the acetic or citric acid. In short, picric acid alone has no visible effect upon mucin, while picric acid with acetic or citric acid causes a mucin haziness in most, if not all, normal urines. One of the most conclusive proofs that picric acid does not coagulate mucin is afforded by the following experiment:—Add to an albuminous urine of normal acidity an equal volume of picric acid solution, then boil so as to ensure the complete coagulation of the albumen, and filter. Add a few drops of acetic or citric acid solution to the clear filtrate, and the result will be, in a minute or two, the appearance of a slight, but perceptible, haze of mucin which the combined influence of picric acid and heat had left in the solution, and so passable through the filter. It is obvious from the foregoing statement of indisputable facts that any test for albumen which requires for its action the combination or the addition of acetic or citric acid is liable to the fallacy that it will give with the mucin present in normal urine an opalescence or haziness which is not distinguishable from that caused by a minute trace of albumen. This remark applies to the tungstate of soda, the ferro-cyanide of potassium, and the potassio-mercuric iodide, but especially to the last-mentioned test. The potassio-mercuric iodide, which, without the addition of acetic or citric acid, gives no reaction with albumen, with that addition causes in most, if not all, normal urines a decided mucin opalescence. I say in *most* normal urines, because although I have found this result in all the normal urines which I have examined, it is possible that there may be some exceptions. It is manifest therefore that picric acid, which requires the addition of no other acid, has a decided advantage over those tests which do require such an addition. It is true that picric acid will not coagulate albumen in an alkaline urine, but an excess of the test is sufficient to acidify most alkaline urines. If, however, a specimen be highly alkaline and ammoniacal, the safest method of procedure is to acidify with acetic or citric acid, then to filter, and add picric acid to the filtrate. The mucin coagulated by the acetic or citric acid will remain on the filter, while the albumen, if present, will pass through. Here, be it observed, the mucin of normal urine must not be confounded with the morbid *mucus* from an inflamed or catarrhal mucous membrane. The mucus which is secreted by an inflamed bladder or urethra or vagina is allied both chemically and microscopically to pus, and, like pus, contains albumen. The presence of morbid mucus in the urine renders the secretion visibly turbid, and the turbidity must be removed by filtration before the tests for albumen can be conveniently applied. Obviously in practice it is of primary importance to distinguish uterine or vaginal, vesical or urethral sources of muco-purulent albuminuria from that which is of renal origin, but it is no part of my present purpose to indicate the means by which this diagnosis is to be made. The result then of the various experiments with picric acid has been to show that *albumen is the only material found in the urine which gives with picric acid an opalescence or a precipitate which is insoluble by heat.* The most delicate test for a minute trace of albumen is to allow the picric acid solution to *mix*, and not merely to come in contact, with about two inches of the upper part of a long column of urine in a test tube, and then to boil the top of the liquid. The more or less turbid upper layer contrasts with the clear urine below. The slight haziness caused by a mere trace of albumen is always increased by heat, while the turbidity caused by urates, &c., is completely removed by heat. If the urine before testing is rendered turbid by urates these must be removed by heat before the picric acid is added, and if by mucus or other floating particles the fluid must be cleared by filtration. When the albumen is very copious the coagulum formed by a few drops of picric acid solution is redissolved, and an excess of the test is required to produce a permanent precipitate. It is manifest, therefore, that the mere *contact* of a column of picric acid solution, without mixture with such a specimen, might give no indication of the presence of albumen. A similar source of error exists in using the so-called "contact method" with nitric acid. I once saw a clinical clerk so carefully pour a column of urine on nitric acid, previously placed in a test-tube, that the two liquids came into contact without mixing. The result was a slight opacity at the junction of the two liquids, and the inference that a mere trace of albumen was present; but as the history of the case had led me to expect an abundance of albumen, I gave the test-tube a shake, when the mixed liquids became nearly solid with albumen. It is a well-known fact that while an excess of nitric acid redissolves coagulated albumen, especially when the mixture is heated, an excess of picric acid has no such misleading effect.

5. It can scarcely be urged as an objection to picric acid as a test for albumen, that to avoid some sources of fallacy the simultaneous or subsequent application of heat is necessary. There is no known single test which, by itself, can be relied upon. This remark is especially applicable to the nitric acid and the boiling tests, each of which employed alone has been, and must continue to be, a source of error.

Picric acid as a qualitative and quantitative test for sugar.—Although my proposal to employ picric acid with potash as a qualitative and quantitative test for sugar in the urine gave rise to a prolonged and somewhat acrimonious controversy, the result of the discussion may be very briefly summarised. It was admitted that when a solution of grape sugar is boiled with picric acid and potash, the yellow picric acid is partially deoxidised and converted into the red coloured picramin acid. This reaction had been observed by Braun, a German chemist, about twenty years ago, but it had never been practically utilised until, "by a happy accident," I rediscovered it.[1] It was also known to chemists that the alkaline sulphides have the same reducing effect as glucose on picric acid, and it was therefore contended that the unoxidised sulphur compounds in urine, and especially in albuminous urine, would form an alkaline sulphide when boiled with caustic potash, and so prove a source of fallacy. I soon found that the practical results were not in accordance with the theoretical objections; for in analysing by the picric acid process a highly albuminous urine, which was also saccharine, one specimen before and another after the removal of the albumen by heat, the results were so nearly identical that for clinical purposes it was not worth while to remove the albumen. And when, before analysing the urine, it was filtered through animal charcoal, so as to remove some colouring matter which appears to be associated with the

[1] See THE LANCET, Nov. 18th, 1882.

Digitized by Google

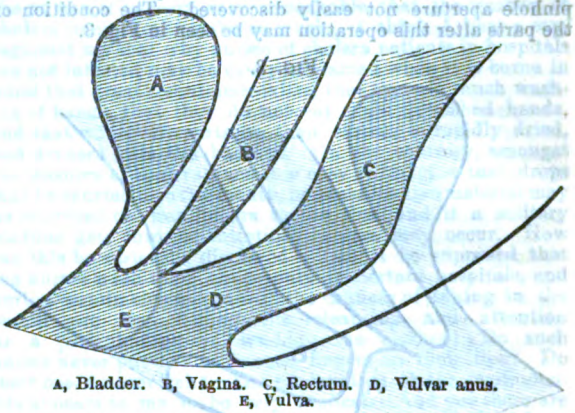
albumen, the results of the analysis of the albuminous and the dealbuminised urine by the picric acid process were found to be perfectly identical. Ultimately my son succeeded in proving to demonstration that the formation of an alkaline sulphide by boiling unoxidised sulphur compounds with potash depends upon the strength of the alkaline solution. When albuminous liquids or other sulphur compounds are boiled with a strong solution of caustic potash an alkaline sulphide is formed. On the contrary, when unoxidised sulphur compounds are boiled with such weak solutions as are employed in testing and analysing saccharine urine no alkaline sulphides are formed, and the picric acid process of quantitative sugar analysis is liable to no such fallacy as theoretical considerations had suggested.[2]

The ready method of qualitative albumen and sugar testing consists in adding to about a drachm of urine in a test tube an equal volume of picric acid solution. This, when boiled in accordance with the rules before given, affords a certain indication of the presence or absence of albumen; then, whether albumen be present or not, add about half a drachm of liquor potassæ (P.B.), and boil for about half a minute. Any coagulated albumen that may be present is redissolved by the alkali, and the resulting colour in a non-saccharine urine is claret red. A good practical rule is that if any red colour is visible through the boiled column of liquid in the test tube, there is less than two grains of sugar per ounce. A solution of glucose in the proportion of two grains to the ounce, after boiling for a few seconds with picric acid and potash, appears quite black until it is diluted with water. Then, having ascertained the presence of sugar, we proceed to make a quantitative analysis by means of the "picro-saccharometer."[3] I have good reason for my belief that practitioners not much accustomed to testing for sugar will find the picric acid method much easier than the copper process. A very common source of error is this, that the slightly coloured phosphatic sediment thrown down by the alkali in the copper solution is mistaken for suboxide of copper, and sugar is erroneously supposed to be present when the urine is perfectly normal.

The materials for bedside albumen and sugar testing may be conveniently and safely carried in a solid form in a pocket test-case, the picric acid in powder and the potash in grain lumps. These, with a small spirit lamp, are all packed into a waistcoat-pocket case by Mr. Hawksley, 357, Oxford-street; or they may be carried in Jahncke's larger, but very pretty, cheap, and convenient case, which was favourably noticed in THE LANCET of September 20th, 1884.

One of the main objects of this communication has been to promote and facilitate the practice of testing the urine in every case of disease, however trivial it may appear. When this practice becomes general, as it ought to be, there will be fewer cases of disease of the kidney passing on to the stage of hopeless and incurable degeneration before they are discovered.

Savile-row, W.



A CASE OF

CONGENITAL VULVAR ANUS CURED BY OPERATION.

By JAMES H. AVELING, M.D.,
SENIOR PHYSICIAN TO THE CHELSEA HOSPITAL FOR WOMEN.

THE subject of this rare malformation was born in 1866, and it was not until she was five weeks old that the unusual situation of the anal orifice was discovered. She was then taken to Sir Prescott Hewett, who made an opening into the rectum in the normal position of the anus. This was kept open by passing bougies more or less frequently for two years. Caustic was applied to the vulvar anus with the intention of causing it to close, but without effect. Up to the age of fifteen the patient was little troubled by the involuntary escape of fæces, constipation being habitual with her, and no motion passing without the use of aperients. At this time a change of residence caused constant relaxation of the bowels, and great inconvenience was experienced. Retention of fluid fæcal matter could only be effected by sitting with the legs tightly crossed. In 1882 she was sent to school at Brighton. While there the relaxation ceased, and although fæces and flatus passed through both openings she experienced little inconvenience. In 1883 the patient began to suffer violent abdominal pains, which induced her mother to relate the whole case to a medical friend, who advised that Mr. Jonathan Hutchinson should be consulted. He saw her, and gave a rather unfavourable prognosis, but recommended the mother to let me see the case, and obtain my opinion as to whether any operation would be feasible and likely to succeed. In February, 1884, the patient was brought to me. She was seventeen years of age and in good health. The catamenia had appeared when twelve years old. A lodgment of hard fæcal matter in the colon had been discovered recently, and to a great extent removed by suitable treatment. On examination I found the malformation, previous to any operation, to have been as depicted in Fig. 1.

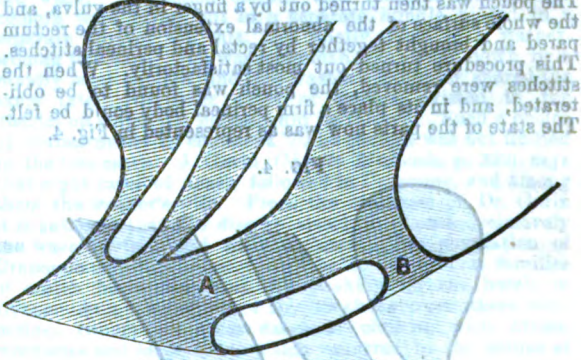


FIG. 1.

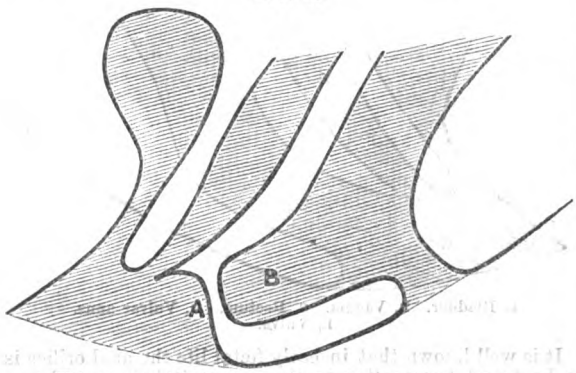
A, Bladder. B, Vagina. C, Rectum. D, Vulvar anus. E, Vulva.

It is well known that in early fœtal life the anal orifice is to be found terminating in the uro-genital sinus, and that this condition of parts continues until the perineum descends and divides the rectum from the vagina. If this developmental action be arrested, what has been called atresia ani vaginalis results. This appellation, at no time very correct, is quite unsuitable in the present case, for the anal orifice was not found terminating in the vagina, but in the vulva, where the fossa navicularis is usually situated. The condition of parts as I discovered them is represented in Fig. 2.

FIG. 2.

A, Vulvar anus. B, Artificial anus.

The vulvar anus readily admitted the tip of the index-finger. Had coitus taken place while this condition of parts existed, the penis would most probably have penetrated the rectum instead of the vagina. The artificial anus was rigid and unyielding all round its margin, and could not be dilated so as to permit of any operative measures being performed through it. Fæces and flatus passed through both openings. Beyond this the patient had no inconvenience, except a feeling of want of support in the perineal region, "tumbling to pieces" when standing or walking. Strange to say, up to within a few months of seeing me she had been ignorant of her malformation, and thought her uncomfortable state was shared by all her sex. In February I endeavoured to close the



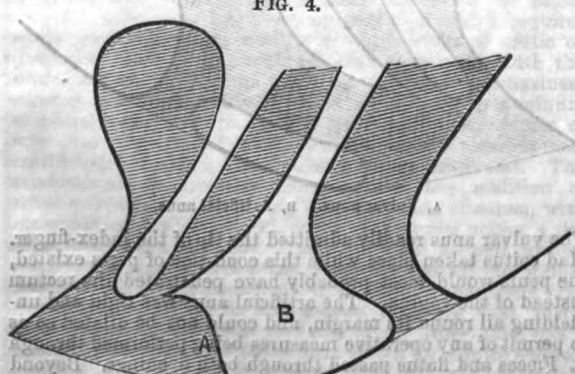
[2] The paper in which my son, G. Stillingfleet Johnson, described his observations On the Action of Potash on Albumen was published in the Chemical News, Feb. 23rd, 1883.

[3] For the details of this easy, rapid, and accurate process I must refer the reader to my pamphlet on Albumen and Sugar Testing, published by Messrs. Smith, Elder, & Co., as may be seen in the advertising columns of THE LANCET.

Digitized by Google

vulvar anus by paring its edges and bringing them together with silver-wire sutures, secured by my shot coils. After the operation the bowels were ordered to be kept free by a small dose of castor oil every morning. The result of this was to bring down a large mass of hardened fæces, which forced its way along the abnormal rectal passage, and tore open the vulvar orifice, entirely defeating the object of the operation. In March, having assured myself that all scybalous masses had been removed, I operated again in the same way as before. The motions were kept fluid, and came away readily by the artificial anus. The flatus, however, forced its way between the stitches on the fourth day after the operation, and caused partial failure. The opening, being reduced to the size of a goosequill, still permitted the passage of fæces into the vulva. In June I repeated the operation, this time passing a small cylindrical speculum through the artificial anus and keeping it in the rectum, so that the flatus might pass through the tube and not reach the recently closed orifice. This plan answered well, and resulted in the vulvar anus being closed, with the exception of a minute pinhole aperture not easily discovered. The condition of the parts after this operation may be seen in Fig. 3.

FIG. 3.



A, Vulvar anus closed. B, Pouch resulting from the operation.

Now another trouble presented itself. The fæces after the oil was stopped became hard, and passed along the rectum to the closed vulvar orifice. There they became impacted, the patient having no power to expel them from this newly formed pouch (Fig. 3, B).

In October I operated for the removal of this condition in the following manner:—The perineal portion of the pouch was divided through the mucous membrane and skin longitudinally up to, but not through, the united vulvar orifice. The pouch was then turned out by a finger in the vulva, and the whole surface of the abnormal extension of the rectum pared and brought together by rectal and perineal stitches. This procedure turned out most satisfactorily. When the stitches were removed, the pouch was found to be obliterated, and in its place a firm perineal body could be felt. The state of the parts now was as represented in Fig. 4.

FIG. 4.

A, Newly formed fossa navicularis. B, Newly formed perineal body.

The result of the operation on the patient was most gratifying. She expressed herself delighted with the change in her local feelings; for besides being relieved from the annoyance of fæces and flatus passing from the vulva, she felt she had lost a sense of weakness and insufficient support in the perineal region. She could hold herself more erect and take longer strides in walking. In the event of her marrying and having a child, she stands a better chance now of escaping serious laceration.

Remarks.—Many women suffering from this malformation have passed through life without any attempt having been made to remedy the distressing infirmity; one even married and had children, and managed to conceal from her husband the abnormal condition from which she suffered. Operative procedures have, however, been adopted in many cases. In some, as in the case I have related, an opening has been made through the perineum into the rectum and an artificial anus formed in the natural situation. The chief difficulty met with in this mode of operating is the persistent effort of nature to contract and heal up the newly made opening. Some cases have failed in receiving relief from this cause, but when the operation proves successful the vulvar opening still remains to be dealt with. A case is related in which this closed spontaneously, but this happy event cannot be expected to happen often. Even the application of caustics has failed to bring about this desirable result. After the formation of an artificial anus Mr. Curling advises that the edges of the vulvar orifice should be pared and brought together by sutures, but I am not aware that this suggestion has been carried out except in the case I have now recorded.

Vicq d'Azyr proposed the following method of dealing with this malformation. He introduced a director through the vulvar opening and divided the skin and rectum as far back as the natural site of the anus. He thus prevented the escape of fæces into the vulva, but left no perineum. His operation cannot therefore be looked upon as satisfactory. Dieffenbach divided the perineum in like manner, but improved the method of Vicq d'Azyr by dissecting the rectum from the surrounding parts and stitching it to the coccygeal angle of his incision. Subsequently he operated for the formation of a perineum. Rizzoli improved Dieffenbach's operation by laying open the perineum without dividing the rectum. This he carefully dissected from its surroundings and transplanted backwards, stitching the vulvar orifice to the skin in the normal anal site. This is undoubtedly the best operation yet proposed, for it preserves sphincteric action, which is lost by all other methods.

My case shows that the closure of the vulvar anus, as proposed by Mr. Curling, is not sufficient. The portion of the rectum between this and the artifical anus must be obliterated. Should I chance to meet with another similar case, I should, by one operation, slit up the perineum and rectum, as in Vicq d'Azyr's method, and having pared the mucous surfaces of the abnormal rectal extension bring them together by vulvar, perineal, and rectal sutures.

Upper Wimpole-street, W.

CHOLERA.

BY MAX VON PETTENKOFER, M.D.,
OF MUNICH.

(*Concluded from page 1043.*)

THE last sheet-anchor of the contagionists is always the linen of cholera patients. But this view rests on such debatable ground that in the end it may prove to be fallacious. If cholera is really spread through human intercourse, then it is clear that the unknown specific something must accompany other vehicles, which may be man himself; and if this something can cause illness in man, then it must reside in the system of the patient, and ought to be found there. There can be no doubt of this; and I am prepared to admit as much. Thirty years ago I began my investigations on cholera in the belief that the germs of cholera were contained in the stools; but afterwards, having made sure that cholera was dependent on locality as well as human intercourse, I endeavoured to see how this relationship obtained by asking myself what was brought to the soil by man in his journeyings. The reply was, urine and stools—his excrements and nothing else. This view ripened into the belief that disinfection of the excreta and their receptacles ought to be a prophylactic measure against the spread of cholera, and excreta which had not been disinfected constituted a source of danger. These thoughts soon

Digitized by Google

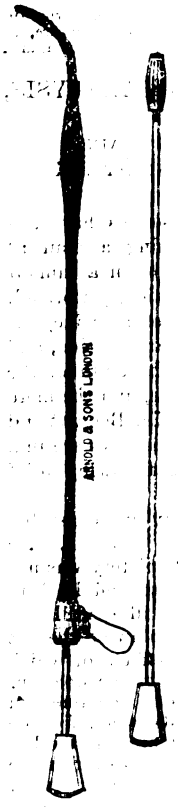
plied me up to April, 1866, when I published with my lamented friends, Griesinger and Wunderlich, some regulations on cholera; and I first relinquished these views when further study showed the uselessness of measures of disinfection as well as the harmlessness of the undisinfected excreta of cholera patients. If the poison of cholera be contained in the excreta, then, individual predisposition aside, those who mostly come in contact with the excreta ought to be most frequently affected. And these should be the various physicians and nurses in hospitals devoted to the care of cholera patients. But experience has clearly shown that the medical attendants in cases of cholera are not more prone to take the disease than others. The like holds good of nurses. Let us first of all consider how the facts stand in the home of cholera, in India. During 1867, in which the epidemic at Hurdwar prevailed, James Cuningham investigated the relationship of cholera to nurses in forty garrison towns containing sixty-seven hospitals; of the sixty-seven hospitals only eight gave instances of cholera in the nurses; the largest number of cases occurred at Dharmsala, where there were eleven, Kasauli had three, Muttra and Moradabad each two, Fazabad, Lakhnau, Mirat, and two others one each. An epidemic amongst the nurses can therefore only be spoken of in the hospital of the 1st Ghorka Regiment stationed at Dharmsala, where eight nurses, two porters, and one other officer were taken ill of the disease. These statements show how exceptional such occurrences are. Why should not a hospital as well as a garrison now and again be a centre of infection? Closer investigation proves, however, that the *personnel* of the hospital at Dharmsala was not affected in a greater degree than the population outside the hospitals. It may be shown that the percentage of cases of cholera amongst the outside population was 8·01; in other words, that eighty-six cases occurred out of 1073, whilst of the hospital staff of 127 eleven fell ill, or a percentage of 8·66. Cuningham also inquired whether the immunity enjoyed by nurses could be explained by disinfection. He found from ancient sources that this striking immunity of nurses was by no means a new thing, and had certainly obtained before the days of disinfection. He draws attention amongst other writings to an experience of Dr. Bruce, who wrote: "In 1848 cholera broke out amongst the infantry at Cawnpur from May to September. During the whole time the hospital was never free from single cases of cholera, and at times it was overfilled with them. The whole institution may be said to have lived in the rooms of the sick; the coolies did not leave the beds of the sick for an hour together, the physicians had much to do with the treatment of the patients; and yet not a man, whether European, half-caste, or native, showed a single symptom of cholera. I took the greatest pains to collect and sift these circumstances, but in this year not a single instance occurred." In India a practical use is made of this knowledge under the exceptional circumstances of the nurses being attacked. Nothing is said of isolation and disinfection; but the site on which the hospital stands is looked upon as unfavourable, and a change is made. This change of place is called by the English a movement, and as a prophylactic measure comes within the first ranks. If the site to which a movement has been made prove to be more unfavourable than that which was quitted —from the frying-pan into the fire,—the movement has not availed anything. No good comes of the movement if the *personnel* has been already infected as much as possible. The 66th Ghorka Regiment in its march through Tarai was not spared when it reached the Naini valley; but, probably, if it had stayed a day longer in Tarai, the percentage of illness, instead of being 10, would have been 20. It is the same as regards nurses and hospitals in Europe. I shall refer to Munich intentionally, not because it had so frequently been the seat of cholera (Munich had cholera once to Berlin's twelve times), but because I am better acquainted with the particulars. During the epidemic of 1873–74 we had three hospitals—the hospital on the left bank of the Isar, in Lindwurmstrasse, and that on the right bank of the river in Müllerstrasse, and the military hospital in Oberwiesenfeld. Cholera behaved in each hospital just as it behaved in the houses in their immediate neighbourhood. Cases of cholera appeared in all three hospitals. In that on the left bank of the Isar there was rejoicing on account of the supposed success of isolation and disinfection until August 15th, when the summer epidemic reached its height; then an epidemic suddenly broke out. This was at the time that the epidemic developed in Lindwurmstrasse, in which the hospital was situate, and the epidemic in the hospital subsided as the epidemic in the street gave way. In the hospital on the right bank of the Isar the rejoicings lasted longer. The Ismaningerstrasse took no part in the summer epidemic, and neither did the residents of the hospital. But in the winter epidemic the same course of affairs took place as had occurred on the left bank of the river. The military hospital escaped all along. Of the seven barracks in Munich any cases or suspected cases of cholera were immediately sent to the military hospital. Now and again a surgical patient or a patient suffering from other illness than cholera was put amongst other patients, and later on suffered from cholera. Such cases were of course removed to the cholera division as soon as the stools betrayed the case. At times the cholera division was very full, and many nurses were employed therein; but none of these fell ill or gave the least indication of cholera, though many of them must have come in very close relation with the cholera stools. In the military hospital in Müllerstrasse the same facts were observed as were met with in the case of the other hospitals. Seeing how little contagious cholera is amongst the nurses, it appears very remarkable that the washers of cholera linen should suffer so much. I think I hear a contagionist say that why nurses of cholera patients in hospitals are not infected may be easily explained when it is borne in mind that great cleanliness exists, that there is much washing of hands, that they do not eat with unwashed hands, and that whatever spurts on their clothes is rapidly dried, and dryness kills the bacillus. On the contrary, amongst the washers of cholera linen it is easy to imagine that drops may be spurted into the mouth, or that infective material may be conveyed on wet fingers to the lips, and if a solitary bacillus gets into the intestines cholera may occur. How can this be seriously discussed? Can it be supposed that the nurses wash their hands only in certain hospitals, and during certain times, and that the chances of taking in the bacilli are less during the cleansing and attention to a patient than in washing the clothes? Do such nurses never put the moistened fingers to their lips? Do their noses never itch? The explanation of the contagionists appears to me to be very comical. And yet there are cases in which the infection must have been derived from the linen soiled by cholera stools. A very interesting case came under my observation at Lyons in the washing villages of Craponne. In the *Gazette Médicale de Lyon* for 1854, page 252, we read from a letter by Dr. Gensoul: "In the month of July, 1854, two fugitives, a man and his wife, from cholera, alighted from Marseilles at the Milanese court. They had hardly arrived before they were attacked by cholera, the germs of which they had brought with them, and both died on July 17th. Some days later the washers of the Gasthof Bouchard in Craponne, a village about twelve kilometres from Lyons, came to fetch the linen for the wash. The soiled clothes and linen of the cases of cholera were given out in a separate bundle, placed in a separate part of the cart, and finally given to a washerwoman to clean. The washerwoman was struck down by a rapidly fatal cholera, and the washer's daughter shared the same fate. No other cases of cholera existed in the district on which the blame could be thrown. Such a choice of victims needs no comment." The cholera was not limited to the two cases. J. Garin (*Gazette Médicale*, p. 399) says that eight cases of death followed in Craponne, and among them the washer's wife. From the statistics of Dr. Garin it is gathered that the disease attacked almost exclusively the washing folk and their children. The population of Craponne numbers about 1600 inhabitants, several families of which have charge of the washing for the hotels of Lyons. As a later report of Dr. Bouchet showed, there were besides twenty-five other cases of cholera, with fifteen recoveries and ten deaths, which occurred in the course of two months. The year 1854 was that in which the lower lying parts of Lyons were invaded by an epidemic. It remains a striking fact that in the fair-sized village of Craponne cholera attacked almost exclusively the laundry workers. With the exception of the washers, Craponne might be regarded as a place free from cholera. In 1855 severe epidemics prevailed in villages near Lyons—e.g., St. Bonnet and St. Laurent de Mure,—though the outlying districts always enjoyed immunity from cholera. The same held good of other exempt districts. A very instructive example of this kind is furnished by Stuttgart in 1854, which is usually exempt from cholera. At the time when the severe epidemic prevailed at Munich an inhabitant of Stuttgart left Munich

Digitized by Google

whilst he was suffering from diarrhœa, and arrived at Stuttgart, where he became worse and died of cholera. A few days later a case occurred in the person of a woman who had never left Stuttgart. She was the nurse of the case which had come from Munich. This case might be quoted as one of direct contagion. Again, after some days, a third case appeared, and this time it was the washerwoman who had cleaned the clothes of the first case. Finally, the washerwoman's husband suffered from cholerine. But no further cases appeared. Such cases are always wrongly interpreted by the contagionists as examples of direct infection, and such, at first sight, appears to be the case. If the case from Munich had infected the three at Stuttgart, how was it that none of the three infected other individuals? For it must be remembered that the cases at Stuttgart and at Craponne must have been tended and their linen washed. How was it that no further cases occurred, and that an epidemic was not started? The linen of the case from Munich was poisonous, but not that from the cases at Stuttgart! Must we not also suppose that another factor is necessary to explain the further spread of cases introduced from without? And this local factor was wanting at Craponne and Stuttgart. If a case from Munich caused three at Stuttgart, then the latter ought to produce nine. In places which enjoy immunity from epidemics it is conceivable that sporadic cases may occur, but the conditions which are necessary for the production of an epidemic being wanting no further development can take place. The soiled linen appears to me to be infective not because it comes from cases of cholera, but on account of its arrival from a locality where cholera prevails. Perhaps linen is a good vehicle for transmitting the infective material produced in a locality under the necessary circumstances of time and place. Man is the only creature that wears linen, and perhaps he alone spreads cholera, and it is possible that whether he were clothed or naked he would spread it just as much and no more. But if we accept this doubtful solution of the Gordian knot, still the views of the contagionists on the dejecta of cholera and the soiled linen would not stand on a firmer basis, since we see not only individual cases but actual epidemics arising without the introduction of soiled linen. The infective material which produces cholera may be transmitted at all events in other ways along the paths of human intercourse. The germs of cholera may be brought from a locality to a place where the necessary relations of time and place are not favourable for the epidemic development of cholera, and they may there slumber for a month before they develop. There is every chance for the propagation of cholera in India, and yet cholera only shows itself fitfully in districts lying outside the endemic area. If the intercourse with India be reduced to the least possible, as it was in the last century, yet cholera might still at times visit us.

Finally, I shall ask myself what can be done to ward off cholera? The measures to be adopted will be very different according to the theory adopted. According to the contagionists the spread of epidemic cholera depends on personal and material intercourse, as well as on conditions of time and space when the germs arrive at certain localities. Moreover, the severity of the epidemic is supposed to depend on the individual susceptibility. If one of these three factors be wanting, an epidemic of cholera cannot develop. Preventive measures against cholera may be devised in one of three directions:—(1) Intercourse; (2) disposition in time and place; (3) individual predisposition. Measures to prevent the spread of cholera by interfering with human intercourse are, for many reasons, impracticable. If we ask ourselves what good has resulted from sanitary cordons, inspection, and quarantine, we are bound to answer, None. All these measures have failed because they simply treat the individual, the possible case of cholera. But the germs of cholera may be transmitted in the absence of the disease as manifested by illness. Even perfect sanitary cordons and quarantine would be also valueless, for the reason that they are commenced too late. It is true that quarantine and cordons may prevent a certain quantity of the germs of cholera from entering a country, so that it will serve as much purpose as a good customs house against smuggling. But there is a great difference between articles of commerce and germs of cholera. The germs of disease are capable of multiplication, and so the smuggling through in a few days, under suitable circumstances, be the means of the development of millions and billions. The epidemics of [illegible] afford excellent illustrations of my argument. Paris has not yet been attacked, whilst all the regulations have failed to prevent the appearance of cholera at Naples. No doubt inspection of ships is a good regulation as tending to discover unhygienic conditions, but it is useless as preventing the transmission of cholera. Inspection of places where cholera prevails, the disinfection of articles coming from localities where cholera is, as well also as the places where the dead are laid, are important matters, but too much is not to be expected from these measures. The prevalence of contagious diseases like small-pox cannot be much diminished by attempts to limit intercommunication. Protection from small-pox by vaccination, which leaves human intercourse free, has been followed by success. But we have not at our command a simple and sovereign remedy by means of which the individual predisposition to cholera may be done away with, and yet we can do something in this direction. Everything which tends to lower the general health and cause depression, but especially those conditions which induce diarrhœa, predisposes to cholera. To these matters everyone must look for himself, and his own efforts may be aided by the advice of doctors. The organs of public health may also effect much. Medical treatment should be obtained for the earliest cases of cholera and of diarrhœa. Care must be taken by the authorities and by the community to take measures for the treatment of the sick. But the difficult point in the prevention of cholera is the predisposition in time and place. It is no use urging, as the contagionists do, that we cannot change the nature of the soil. One of the established facts concerning epidemics of cholera is the tendency of the disease to rage in those quarters where the greatest filth prevails. All towns which have been provided with good drainage and water-supply have lost their susceptibility to cholera. England affords the best example of this fact. In 1849 there were recorded 53,237 deaths from cholera, in 1854 the numbers were 20,097, and in 1866 only 14,378, whilst from 1872 to 1874, when several epidemics prevailed on the Continent, cholera did not reach England. I do not imagine that this immunity was due to the want of predisposition to cholera as regards conditions of time. The case of Fort William in Calcutta may be again referred to, as there, I believe, the immunity from cholera now enjoyed was due not merely to the introduction of a better supply of water, but largely also to the improvement in other matters of hygiene.

Seestaupt, August, 1884.



A NEW FORM OF DILATOR FOR STRICTURE OF THE URETHRA.

By W. J. WALSHAM, F.R.C.S.,
ASSISTANT SURGEON TO, AND DEMONSTRATOR OF ORTHOPÆDIC AND PRACTICAL SURGERY AT, ST. BARTHOLOMEW'S HOSPITAL.

THIS instrument, which is made by Messrs. Arnold and Son, of West Smithfield, may for the purpose of better describing it be said to consist of four parts: 1. A central solid steel staff or director, the size of a No. 1 catheter (English gauge). 2. An arrangement around this of a dozen or so of thin steel ribs, welded together at their distal ends, so as to form with the end of the central staff the curved extremity of the instrument; and inserted at their proximal ends at a distance of one-sixteenth of an inch apart into a metal ring, the size of a No. 14 catheter (English gauge). This ring is provided with a short flattened handle, to indicate the direction of the point of the instrument. 3. A series of bulbous-ended hollow rods of graduated sizes for sliding over the central staff. The bulbous extremities are grooved longitudinally, the number of grooves corresponding to the number of wires surrounding the central staff. When one of the hollow rods is slipped over the central staff, the grooves in the bulbous end slide along under the wires, separating them from one another, and expanding the instrument to the size of the bulb as the hollow rod is pushed home. 4. A long conical indiarubber sheath, which fits closely over the wire ribs, keeping them in contact with one another and with the central staff, and so rendering the instrument (when not expanded) to all intents and purposes a solid bougie. On passing one of the dilating rods the wires are separated by the bulb; but the instrument, unlike some others, is expanded, not

Digitized by Google

through its whole extent, but only at the situation at which the bulb may happen to be as it travels along the central stem. The indiarubber covering ensures expansion of the wires in all directions equally, and prevents the mucous membrane of the urethra from being caught between them when the dilating rods or the whole instrument is withdrawn. After use the sheath can be readily removed from the wires and cleansed by immersion in some antiseptic fluid, or, as it costs but a mere trifle, a fresh one can be used on each occasion if thought more desirable. In using the instrument the rod with the smallest bulb should first be passed, and then successively one with a larger and larger bulb till the tissues composing the strictures have been thoroughly stretched, and the urethra in its proximity has been dilated a size or two beyond its normal diameter. Each rod should be passed very slowly (not thrust violently home, as in using a Holt's dilator), so as to stretch rather than to tear the tissues forming the stricture. If this is done, no deep laceration of the urethra need be produced, and very little, if any, bleeding will follow the withdrawal of the instrument.

The advantages of this dilator are (1) that as the bulb is pushed home the wires are expanded immediately in front of it in the form of a conical wedge, so that the stricture is gradually stretched, and not suddenly ruptured, as happens in the use of some so-called dilators; (2) that the expansion of the instrument takes place equally in the whole of its circumference; (3) that the indiarubber sheath renders it exceedingly soft and non-irritating, and prevents the mucous membrane of the urethra from being caught on withdrawing the instrument; (4) that as the steel parts of the dilator are entirely covered by the indiarubber sheath, they are preserved clean and dry, thus dispensing with the tedious cleaning otherwise required; and as a new sheath can be used on each occasion, all danger of septic infection is avoided.

I am not advocating the treatment of stricture of the urethra by means of dilating instruments, such as the above, in ordinary cases, as against the well-known methods in daily use; there are, however, exceptional cases in which treatment by means of dilators is indicated, and for such I believe the present instrument will be found to answer the purpose better than any other with which I am acquainted.

Weymouth-street, W.

A CASE OF
ACUTE ASCENDING PARALYSIS (LANDRY'S).

By H. MARTYN CLARK, M.B., C.M. EDIN.,
IN CHARGE, UMBRISUR MEDICAL MISSION HOSPITAL.

On account of the great rarity of this disease the following case of Landry's paralysis seems to me to be worthy of record.

F. D——, a Mahommedan lad, aged sixteen years, was admitted into the Mission Hospital. He was suffering from paralysis of the lower extremities; he complained of pain, and tingling and pricking sensations in the affected parts. The following history was obtained. The lad had enjoyed excellant health up to the time of the seizure. There was no history of syphilis, gout, or rheumatism; the family history was good. Five days previous to date of admission he on rising in the morning felt himself to be considerably "out of sorts." During the day he noticed that his legs seemed very heavy and weak; this caused him slight difficulty in walking. The next day the weakness and consequent difficulty had become greater; the limbs dragged; he was unable to continue at his work. On the third day there was complete paralysis; this became no better, but seemed steadily to increase. On the fifth day he was brought to hospital. Every now and then shooting pains occurred, but these were slight. At no time had he given much pain, but there had been a good deal of formication, pricking, and tingling in the limbs. An examination showed the lad was well nourished, and to all appearance healthy. There was complete loss of motor power in the lower limbs; this extended to the waist; above this the movements were unaffected; beyond the slight pain and abnormal sensations there were no sensory changes in the affected parts; thermal and muscular sense were normal; there were no vaso-motor or trophic changes; skin reflexes were normal in character but tendon reflex was markedly diminished. The organic reflexes were unaffected at the time of admission, as were the cerebral and mental functions; the other systems of the body were all normal. For want of proper apparatus the electrical condition of the paralysed parts could not be ascertained.

The day after admission the urine and faeces began to pass involuntarily and paresis of the muscles of the trunk and arms began to appear. This gradually deepened until on the third day after admission (the eighth day of the disease) there was complete motor paralysis of the trunk and arms. The intercostal and abdominal muscles were implicated and the respiration was carried on mainly by the diaphragm. The lad was thus paralysed from the feet to the arms. The sensory, vaso-motor, trophic, mental, and cerebral functions remained unaffected as before. At this point the patient was, much to my regret, removed by his friends, so that I am unable to state how the case terminated.

Remarks.—The sudden attack of weakness of the legs passing into profound motor paralysis, unattended by any sensory, vaso-motor, trophic, mental, or cerebral change, led us to diagnose Landry's paralysis, and the subsequent rapid extension of the disease upwards confirmed us in our diagnosis. This is a rare disease of the spinal cord, consisting in lesions which are as yet unknown; it usually ends in death by implicating respiration, or by extending to the medulla. Sometimes it becomes arrested and the patient recovers. No treatment has been found of any avail in this case; beyond general measures none was adopted.

A CASE OF
RETENTION OF URINE IN AN OLD MAN; PUNCTURE OF THE BLADDER ABOVE THE PUBES.

By FREDERICK W. STORRY, M.R.C.S.,
SURGEON TO THE STROUD HOSPITAL.

On Sept. 29th of this year I was called to an old man three miles in the country, about four o'clock in the afternoon, with a message that "he had not passed any water all day." I found him in bed suffering all the anguish of a distended bladder, unable to pass a drop of urine. He was ninety years of age. Fourteen hours previously he had micturated, and then for the first time in his long life he noticed some difficulty. I attempted to pass a No. 8 catheter, but failed. I then sent for more instruments, and tried a gum-elastic French coudée and silver catheters of all shapes and sizes, but signally failed to make one reach the bladder. Unfortunately, after an hour's struggle, I made a false passage, which relieved him of a couple of ounces or so of blood. I had examined him by the rectum when I first saw him, and found a large mass in the situation of the prostate, beyond which my finger could not reach; therefore puncturing the bladder per rectum was out of the question.

Having had ether administered to the patient, I cut down upon the linea alba just above the pubes, and tapped his bladder with the ordinary trocar and cannula for tapping through the rectum. I relieved him of a quantity of urine, but had no opportunity of measuring the exact amount. I left the cannula in the bladder for three days, then removed it, and replaced it by a gum elastic catheter cut to the proper length. Daily for a fortnight I removed this instrument, and washed out his bladder through this artificial opening. I have attempted frequently to pass an instrument into the bladder by the urethra since the operation, but have failed. The urine is now quite clear, and the old man is in comfort and great satisfaction at seeing his urine flow from him when he removes a

Digitized by Google

spigot of wood at the end of a shortened catheter. He now removes the catheter, washes it, and puts it back again daily. He is up from his bed daily for a time, but is certainly losing flesh. Whether the mass felt through the rectum is due to simple hypertrophy of the prostate, or to a new growth in that organ, remains to be proved. Since the operation the mass certainly feels larger.

Stroud.

TOTAL SUPPRESSION OF URINE FOR NINE DAYS; RECOVERY.

BY D. S. SHROFF, L.R.C.P. & S. EDIN.

I SAW a Mahommedan on Sept. 4th; he was about fifty-four years old, in a fair condition of body. His complaint was that he had passed no urine since the previous morning, and that he felt heaviness in the head and suffered from vomiting. He attributed his illness to keeping late hours during the last two nights. Present condition: The abdomen was moderately distended, and there was neither fulness nor dulness above the pubes. All the abdominal viscera were normal, and so were the thoracic, except that the sounds of the heart were weak, the pulse being 70, soft and feeble. Pupils were slightly dilated, but there was no conjunctival redness. There were headache, vomiting, and drowsiness. On the 4th, being requested, I passed a No. 9 catheter, which went in very smoothly, but not a drop of urine passed out, except that when I took it out a few drops of reddish urine trickled down. This total suppression continued till the 12th. To sum up, the symptoms present during the space of nine days were as follows:—Drowsiness, drooping of the lids, pupils slightly dilated, headache, extreme weakness, slight pain in the lumbar regions, puffiness of the abdomen, and constipation. There was vomiting, which was severe at times, but not always. The patient retained about two doses and a half of medicine out of four, about half a cup of soup, a cup of milk, half a bottle of soda-water, and about half a cup of barley water in twenty-four hours. Thirst was absent, and there was neither delirium, coma, nor fever.

Treatment.—I had a great mind to inject pilocarpine, but the patient would not consent. My plan was as follows: Hot vapour bath in the morning, which produced copious perspiration, hot hip bath in the evening, and fomentation on the abdominal and lumbar regions twice a day. The trunk all round the abdomen was well covered with flannel, and the feet were kept warm, but the head cool. Internally I gave stimulating diuretics and an occasional saline purge. Every evening I gave an enema of castor oil with soap-and-water to relieve distension as well as constipation. On the tenth day, September 12th, the patient passed a few drops of bloody urine three times from morning till evening. On the 13th at 8 A.M. twenty-four ounces of urine were passed; it contained very little albumen and deposited some mucus. An enema at 9.30 A.M. was given, which was followed by a copious semi-solid stool. Only two doses of medicine were taken and retained. On the 14th at 2 A.M. thirty-five ounces of deep-red coloured urine were passed with one motion. On the 15th at 6 A.M. five ounces of straw-coloured urine were passed. Two doses of medicine were retained. On the 16th in the morning forty-five ounces of urine were passed, the first eight ounces were bloody. An enema was given at 7 P.M., which was followed by a copious semi-solid greenish-yellow stool. Only one dose of medicine was taken. On the 17th from evening till next morning some urine was passed every three-quarters of an hour, the total quantity measuring about fifty ounces. It was of pale-straw colour and deposited mucus; but there was no albumen in it. One dose of medicine was taken. On the 18th—i.e., on the sixteenth day from the total supression—the urine became normal in quantity and quality. After he began to pass water I stopped the baths but continued the fomentation. He had slight vomiting and slept longer, but complained of utter prostration.

Calcutta.

HOSPITAL SUNDAY AND SATURDAY.—The Hospital Sunday collections in Birmingham this year amounted to £4674, and the Hospital Saturday collection at Exeter realised £400.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK.

EXCISION OF A TUMOUR FROM THE BRAIN.

(Under the care of Dr. HUGHES BENNETT and Mr. RICKMAN J. GODLEE.)

DURING the last few weeks several notices have appeared in various medical papers concerning a man at present in the above hospital, from whose brain a tumour has been successfully removed. This operation, performed, we believe, for the first time in the history of medicine, has naturally attracted much notice amongst the profession, and numerous inquiries have been made as to the truth of the reports. Pending the termination of the case, and the more complete and scientific account of it which Dr. Bennett and Mr. Godlee will doubtless subsequently publish, we are in a position to furnish our readers with the following brief narrative of facts.

Some weeks ago a young man, aged twenty-five, consulted Dr. Bennett, complaining of paralysis of the left arm. He stated that he was a farmer, that his family history was unimportant, that he had always led a temperate and healthy life, and that he had never suffered from any illness till four years ago. About this time he received a blow on the left side of his head from a piece of timber, the effects of which were temporary and did not interfere with his occupation. With the exception of occasional headaches he remained in his usual good health for a year afterwards, when for the first time he began to experience slight twitchings in the left side of his face and tongue. These gradually became more pronounced, and occurred paroxysmally at irregular intervals. Soon afterwards he was seized with a "fit," which began with a sensation in the left side of the face and tongue, running down the left side of the neck to the arm and leg, and culminating in general convulsions and loss of consciousness. For two and a half years, although maintaining his robust general health, he was subject to daily recurrences of these paroxymal twitchings in the left side of the face without loss of consciousness, and to the more severe general convulsive seizures with loss of consciousness which occurred on an average about once a month. Six months ago for the first time he was attacked with spasmodic twitchings of the left hand and arm, and these continued daily to alternate with the twitchings of the face, the two rarely occurring at the same time. These continued till the patient came under observation. Since the affection of the arm began there has been no recurrence of the general convulsive seizures with loss of consciousness. Shortly after, weakness of the left hand was observed, and this paresis of the upper extremity has continued slowly to increase up to the present time. The patient was, however, able to continue at work till three months ago, when the weakness of the arm prevented him using his tools. Since then twitchings of a similar nature have taken place in the left leg, and subsequently in the left eyelid, occurring in paroxysms several times a day. Quite recently the left lower extremity was found weak, and the patient walked lame.

On examination the patient was found in robust general health. His intelligence as well as all his organs and functions were normal, except those about to be described. He suffered from frequent and violent pains in the head diffused over the vertex. There was nothing abnormal to be seen on the scalp, but on firm deep-seated pressure there seemed to be tenderness in the upper parietal region a little to the right of the middle line. The movements of the eyeballs and pupils were normal. There was well-marked double optic neuritis, most marked in right; but vision was normal. There was slight comparative immobility of the left side of the

Digitized by Google

face. The tongue when protruded pointed slightly to the left. Articulation seemed natural. Hearing normal, but somewhat less acute on the right side. There was complete paralysis of the left fingers and wrist, very limited movements of the elbow, and at the shoulder these were greatly impaired. The left lower extremity was weaker than the right, and although the patient could walk he did so with a limp, and swinging his left leg, as he could not clear the toes from the ground. The mechanical irritability of the muscles, the knee jerk, and the ankle clonus were most marked on the left side. The sensibility of the skin was everywhere normal, and there was nowhere any muscular wasting.

While under observation the patient suffered from violent paroxysms of lancinating pain in the head, which at times rendered him nearly delirious. He also was frequently seized with attacks of uncontrollable vomiting, which sometimes continued for days together and prevented his taking nourishment. The twitchings which occurred many times a day without loss of consciousness were also noted. These usually began in the fingers and thumb of the left hand, and consisted of rapid rhythmical movements lasting for a minute or two. These were sometimes confined to the arm alone, and sometimes to the face alone. Occasionally they began in the face, and from there extended to the arm, and down the leg of the same side. They were never observed in the leg alone.

These, briefly stated, are the chief symptoms which this patient presented. Combined with a general consideration of the facts of the case they led Dr. Bennett to arrive at the following conclusions. First, that there was a tumour in the brain; secondly, that this growth involved the cortical substance; thirdly, that it was probably of limited size, as it had destroyed the centres presiding over the hand, and only caused irritation without paralysis of the centres of the leg, face, and eyelids which surround it; and fourthly, that it was situated in the neighbourhood of the upper third of the fissure of Rolando.

This diagnosis having been made, Dr. Bennett suggested that the tumour be cut down upon and removed. He was all the more encourged to propose such an operation as the sufferings of the patient had become intolerable. All the risks were fairly explained to the man, who cheerfully consented to any procedure which offered any prospects of relief. Accordingly, on Nov. 25th Mr. Godlee trephined the skull, and removed a triangular piece of bone over the region corresponding with the upper part of the fissure of Rolando. The surgical details need not here be entered upon, as these, with the other more precise facts of the case, will be subsequently brought before the profession. It is at present sufficient to say that even after the bone was removed, the dura mater slit up, and the cortex of the brain exposed, no tumour was visible. The ascending frontal convolution, however, seemed to be somewhat distended. An incision about an inch long was made into the grey matter in the direction of the bloodvessels, and a quarter of an inch below the surface a morbid growth was found. This was carefully removed, and proved to be a hard glioma about the size of a walnut. The superficial part of this was distinct from the brain matter and was easily enucleated. The hæmorrhage was arrested by means of the galvano-cautery and the wound brought together by sutures.

Since the operation up to the present time (Dec. 15th) it may be said in general terms that the condition of the patient has been satisfactory. At no time has the temperature been above 100°, or the pulse over 90 beats per minute. The patient has throughout been perfectly intelligent, and now is cheerful, and expresses much gratitude at the result of the operation. He has totally lost the lancinating pains in his head, the vomiting, and the convulsions of his limbs; his appetite is excellent, and all his functions are naturally performed. The state of the wound has given rise to some anxiety, as a hernia formed, consisting for the most part of clot and granular matter, which was shaved off. This caused the flaps in the scalp to gape open, and these have not yet healed. This, however, does not seem to cause the patient any inconvenience. Since the appearance of the hernia cerebri the paresis of the left leg has increased, but how much this may improve it is at present impossible to conjecture.

We need scarcely observe that the further progress of this man will be watched with the greatest interest by all those who appreciate the important physiological and clinical principles involved in the case.

BRADFORD INFIRMARY.

TWO CASES OF DOUBLE OÖPHORECTOMY.

(Under the care of Dr. RABAGLIATI.)

FOR the following notes we are indebted to Mr. W. J. Spence, house-surgeon.

CASE 1.—Sarah S——, aged twenty-six, married, a slight-built, delicate looking woman, was admitted during December, 1882, complaining of a constant pain, which at times became most excruciating, affecting the left iliac region. Prior to admission she had been under the care of several practitioners, and had been in hospital three times. The remedies had been many and varied; a variety of instruments had been worn, all of which increased rather than diminished the pain. Posterior hysterotomy and dilatation of the os had been tried, blisters, baths, and innumerable medicines, but all to no purpose; the patient gradually got worse, until lately life had become, to use her own expression, unbearable. The pain, which increased on deep pressure, commenced six years ago (six months after marriage) with what she says was an inflammation of the bowels. It was at first intermittent, being sometimes free for days together, but of late it had become constant. Menstruation began when she was seventeen years of age, and has continued at irregular intervals ever since. She has never had any children. The sound passed two inches within the cavity of the uterus, causing great pain; there was slight retroflexion.

After a consultation with Mr. Miall, Dr. Rabagliati decided upon removing the ovaries as a last resource. The serious nature of the operation, with its results, was plainly put before the patient, but she urgently pressed for the operation, preferring it with all its risks to the suffering she was undergoing. The operation was performed on Aug. 10th with strict antiseptic precautions. The ovaries, together with their appendages, were removed through an abdominal incision from three to four inches in length; silkworm gut was used to secure the pedicles. Both ovaries were found to be enlarged, cystic, and adherent to the surrounding parts. On section they appeared injected, but there was no sign of suppuration. The Fallopian tubes were greatly dilated.

The wound healed by first intention and the patient made a good recovery. She has been seen at frequent intervals since the operation and expresses herself as quite a new woman, the old pain having entirely disappeared.

CASE 2.—Elizabeth L——, housewife, aged twenty-eight, was admitted on March 29th, 1884, complaining of severe pain in the right iliac region. The patient stated that menstruation commenced when she was sixteen years of age, and had continued at regular intervals ever since. The menstrual discharge was normal in quantity and appearance. She was married three years ago and delivered of a female child eleven months later. The child was brought up by hand and is alive and healthy. The labour was tedious, lasting twenty-three hours after rupture of membranes. She made a good recovery, being up and attending to her household duties at the end of a fortnight. The catamenia appeared two months afterwards. She has since been regular. About three or four months after the child was born she began to be troubled with pain in the region of the right ovary, it was, at first, intermittent and slight in character, but gradually increased in severity; it became constant and extended to the back and down the thigh of the affected side. Of late it had become almost unbearable. Her medical attendant, Mr. Miall, tried all the usual remedies, but without any relief.

After a consultation with Dr. Rabagliati, and at the patient's urgent request, it was decided to remove the ovaries, and for this purpose she was removed to the infirmary. Upon admission the pain was found to be located in the right iliac region and was increased upon deep pressure. The uterus was normal in position and appearance and the sound entered nearly two inches. The operation was performed under chloroform administered on a towel at 9 A.M. on April 9th. Strict antiseptic precautions were observed. The ovaries and their appendages were removed through a median abdominal incision three to four inches in length. Silkworm gut was used for the pedicle, as in the last case. The wound was closed by deep chromic catgut sutures, which included the peritoneum as well as the remainder of the structures forming the abdominal wall. Before the chromic sutures were tied the cut edges of the peritoneum were brought together by fine catgut sutures. Some superficial

Digitized by Google

ones were also used to bring the skin into more accurate apposition. The right ovary was found to be cystic and the corresponding Fallopian tube somewhat constricted. The left ovary was also cystic, but the Fallopian tube appeared normal. During removal of the left ovary a large superficial cyst was ruptured.

There was slight sickness during and immediately after the operation, but none afterwards. For the first twenty-four hours the patient was allowed nothing but ice. On the second day a little milk diluted with water was given. On the fourth day there was slight appearance of catamenia, which lasted three days. The case ran a most favourable course; the temperature was never higher than 100·8°, the wound healed by first intention, and was quite sound on the ninth day. The patient was discharged cured at the end of the month. The patient has been seen at frequent intervals, and expresses herself as quite relieved. The old pain has entirely disappeared.

SOOREE CHARITABLE DISPENSARY.

CASE OF LIVER ABSCESS TREATED WITH FREE INCISION AND DRAINAGE; RECOVERY.

(Under the care of Dr. G. C. ROY.)

W. W——, aged about thirty years, a Mahommedan constable, presented himself for treatment on June 4th, 1882. He was very emaciated, and so weak that he had to be lifted from his bed. He was subject to malarious fever off and on. About three months before admission he had fever of low remittent type, followed three days after by pain over the liver, which had continued ever since. He was habitually addicted to spirituous liquor.

On admission his pulse was very weak and quick; tongue clean; bowels confined; appetite poor. The liver dulness extended to one inch below the costal cartilages, but at the side there was a uniform bulging with fluctuation and pain on pressure. No jaundice.

An incision about an inch in length was made on the seventh intercostal space in the axillary line under carbolic spray, and the cavity of the abscess was reached. About sixteen ounces of pus mixed with blood were evacuated; a drainage-tube eight inches in length was introduced and covered with a padding of cotton saturated with corrosive sublimate lotion and tied, and the whole secured by a body bandage.

The discharge continued free, being of the same colour and consistence. There was no accumulation of matter even when the cavity was sucked out by the aspirator. Weak carbolic lotion was injected for two days, but it produced strangury and symptoms of carbolic poison. The discharge gradually got less, and as the cavity contracted the drainage-tube was shortened, till on the 25th it came out altogether. On that date there was hardly any discharge, still he was kept under observation for four days, and discharged on the 30th with the liver reduced to its normal size; appetite was good, and the patient was then going about the hospital.

A CASE OF IMPERFORATE ANUS AND PREPUCE.

(Under the care of Dr. G. C. ROY.)

A child was brought three days after birth with absence of anal aperture. It was said that it had not passed water or any stool. The abdomen was swollen, the breathing was laboured, and its general condition was low.

In front of the coccyx and in the median line there was a slight depression, over which an incision was made and dissected down to the extent of one inch, but no dilated cloaca was found. A coil of intestine was felt, and as the child strained it was hooked down by a bent probe and opened, when meconium flowed out freely. There was closure of the prepuce producing phimosis, which was also circumcised. As after operation the child's condition seemed critical, no further manipulation was attempted, but it was put to the breast, and the mother was asked to come the next day. Nothing more was heard of it for ten days or a fortnight, when the mother returned with the child well developed for further relief, as the artificial opening was contracting and a fæcal sinus had formed in the scrotum. On probing the latter it was found to pass under the skin and communicate with the former. The sinus was laid open in two operations throughout its entire length, and at the lower part the bowels were found to be superficial and adherent to the skin. This opening was situated in front of the previous one, and was continuous with it. It had formed for itself a sort of mucous lining. The bowels continued to be discharging through this without any impediment, and the mother was asked to reappear after a month if there was any tendency to closure. The child was brought afterwards for observation, looking healthy and with no tendency to contraction of the artificial anus.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Intestinal Obstruction produced by Gall-stones.—Gunshot Injury of Brain.—Sympathetic System in Diabetes.

AN ordinary meeting of this Society was held on Tuesday last, Mr. J. Whitaker Hulke, F.R.S., President, in the chair.

Dr. PAYNE read the report of the Morbid Growths Committee on Drs. Lanchester and Hobson's case of Caseous Pneumonia. In some parts of the lesion, tubercle, with well-marked giant cells, were to be seen; and the lymphatic vessels contained much granular matter. The remarkable uniformity of the changes throughout the lungs was evidence of the age of the various parts being the same. The fibrous exudation in the alveoli, which had undergone fatty and granular change, as well as the fibrinous nature of the morbid products, pointed to the conclusion that the case was one of acute lobar fibrinous pneumonia, which had ended in caseous degeneration, and had been accompanied by acute tuberculosis. Usually caseous changes were the result of lobular catarrhal processes, and so this case was very rare. Possibly Addison had described the disease, but Cornil certainly had, under the term "pneumonie caséeuse lobaire," and as a secondary accompaniment of tuberculosis. Whether the pneumonia or tuberculosis were primary it would be difficult to decide.

Dr. S. WILKS showed, for Mr. Wilks of Salisbury, some specimens of Gall-stones which had caused intestinal obstruction. The patient was a single woman, aged forty-two, who suffered for seventeen days from obstruction of the bowels. She was first seen on Nov. 5th, 1884, when constipation had lasted two days; there was not a great distension of the abdomen, but some sickness was followed later by stercoraceous vomiting, and the symptoms lasted until Nov. 21st. Then an enema was given and brought away a large stone which was floating in the bed-pan; on the 22nd a second stone came away embedded in fæcal matter. Reference was made to a drawing in Frerich's work which bore on the case. The bigger stone had a concave facet and weighed 250 grains; it measured 1½ in. by ½ in., and was 3½ in. in circumference. The other stone weighed 130 grains, and measured ¾ in. in length. In the Pathological Transactions similar cases had been reported by Dr. H. Fagge, and Dr. Murchison believed that the stones formed in the gall-bladder and then made their way directly into the intestine. In this case there was no previous history of gall-stone or jaundice. It was generally believed that the cause of obstruction was outside the intestine, and so the present case was very exceptional.—Mr. HULKE asked at what part of the intestines it was supposed that the stone had lodged.—Mr. JOHN WOOD referred to a case on which he operated some months ago. There was a painful tumour about the gall-bladder, and adhesions existed between the gall-bladder and the wall of the abdomen. Careful dissection was made, and then thickened tissue connected with an abscess containing two gall-stones of the size of a small nutmeg was detected in contact with and adherent to the hepatic flexure of the colon. He had, in fact, intercepted the passage of the gall-stones from the gall-bladder to the colon.—Mr. HULKE referred to a case in which a large round knob was felt in the rectum, and had acted like the ball of an ordinary valve causing obstruction, which was easily relieved.—Mr. CLEMENT LUCAS said that the stone could not have obstructed the colon.—Mr. F. TREVES thought every possible evidence was in favour of the view of Dr. Wilks, that gall-stones ulcerated directly into the intestine. He had collected forty-eight cases of obstruction, due to gall-stones. Of these thirty-two were to be found in a paper by Leichtenstern. In the majority of cases direct evidence of ulceration between the gall-bladder and duodenum was to be obtained. Stones which measured three inches in cir-

Digitized by Google

cumference could hardly have passed down the common bile-duct which, however, might be dilated to the size of the thumb. The gall-bladder was entirely disorganised in a case in which the gall-stone was supposed to have traversed the bile-duct. Sometimes ulceration took place between the gall-bladder and the hepatic flexion of the colon. The obstruction was situate in the lower part of the ileum in 50 per cent. of the cases. The upper part of the jejunum was the next most frequent site of obstruction. Foreign bodies were liable to set up inflammation of the bowel, and this might go on to gangrene of the intestinal wall, and so it could be understood how aperients were more likely to do harm than good. The largest stone which has been successfully passed was 3½ in. in circumference.—Mr. A. E. BARKER referred to a case which was published in the twenty-ninth volume of the Pathological Transactions. It was that of a lady, aged fifty, who died from exhaustion after stercoraceous vomiting. The stone was 4½ in. in its greatest circumference, and had plugged the upper part of the ileum. Ulceration and dilatation of the common bile-duct might allow of the passage of large-sized stones.—Dr. WILKS was of opinion that in this case the stone had probably stuck in the rectum.—Dr. GEORGE HARLEY said that ulceration of the gall-bladder frequently took place into the intestine, and that was the route by which gall-stones of some size had passed, and this explained the absence of jaundice or clay-coloured stools.—Dr. GOODHART spoke of a case in which the stone had ulcerated into the duodenum and set up hæmorrhage by attacking the portal vein. The lower part of the ileum contained a stone which was closely hugged by the muscular coat of the bowel. Such stones were not big enough *per se* to block either the intestine or the colon.—Dr. CARRINGTON also mentioned the case of an elderly lady who suffered from attacks of gall-stones from time to time, and in whom intestinal obstruction set in. The stone was not large enough to obstruct the ileum though it was firmly impacted a little above the cæcum in the ileum. Death had resulted from acute peritonitis due to rupture of adhesions about the duodenum.

Mr. W. ROSE read the clinical notes of the case of Gunshot Injury of the Brain. The patient was a solicitor, aged forty-five, who had been drinking heavily for a week. The revolver was fired, in an attempt at suicide, into the mouth, the bullet penetrating the hard palate and passing upwards through the anterior part of the brain. On admission the ragged aperture of entry was seen immediately behind the incisor teeth; the aperture of exit was not to be detected at that time. There were great tumefaction and tension of the tissues of the scalp, and the features had become unrecognisable. There was extravasation of blood into the eyelids, but no subconjunctival hæmorrhage could be detected until two days later. There was no motor or sensory paralysis, and no pain. The intelligence of the patient seemed fully preserved. On the fourth day the swelling had subsided, and an antiseptic operation was undertaken with a view of removing the bullet, which together with a fracture were detected in the right frontal region. Much clotted blood and brain matter were taken out, as well as several pieces of bone, and the bullet in two portions. The patient died fourteen hours later from exhaustion.

Dr. H. SAINSBURY read notes of a case of Gunshot Wound of the Brain. The bullet had traversed the ethmoid plate and pierced the right frontal bone close to the mid-line one inch in front of the coronal suture. The damage to the brain included extensive subdural and subarachnoid hæmorrhage. There was superficial laceration of the left orbital convolutions, corresponding to the situation of the ethmoid bone, and deep laceration of the corresponding parts of the right orbital convolutions. The further course of the bullet was limited to the right hemisphere; in front of a vertical line at the anterior border of the bend of the convolution of the corpus callosum there was complete destruction of the marginal convolution; this involved partial destruction of the first frontal convolution in front of the same line. The immediate symptoms in this case were negative; there were no sensory or motor effects of any kind, and, further, the patient was rational. The case is of interest from the position of the lesion and the complete accordance of the results of the lesion with the doctrine of "cortical localisation." The special value of the case lies in the damage done to the marginal convolution, the results again considered in relation to this being in agreement with the recent experiments of Horsley and Schäfer. The absence of any disturbing element in the shape of effects from altered intracranial pressure was owing to the very free drainage which obtained through the base of the skull. Finally, the importance of immediate symptoms in the consideration of lesions of the nerve centres was insisted upon. Immediate symptoms were those occurring after the disappearance of shock. The universal intercommunication of nerve centres, both in the spinal cord and cerebral cortex would necessarily imply the possibility of the opening up of side paths in the event of blocking of the main channels; and hence there was a possibility of a lower centre cut off from its higher centre still receiving stimuli from the opposite cerebral hemisphere. Hence in process of time there would occur the removal of the primary effect even though the original blockage should have persisted. The doctrine of the association of centres would be an exemplification of this doctrine of the general intercommunication of nerve centres. This anastomotic or supplemental action would probably account for many experimental and pathological discrepancies. The latency of symptoms in slowly growing tumours of the brain might receive an explanation from these considerations.—Mr. CLEMENT LUCAS said it was quite clear that the subarachnoid space had been opened above and below the hemisphere, and asked whether the evidences of this lesion were present.—Dr. RICHARDS referred to the case of a boy who received a sort of bullet wound in the right parietal region of the skull, and in whom for forty-eight hours there were no symptoms. The boy died suddenly, and then two ounces of lead were found close to the central ganglia of the brain. It was supposed that the lead had gravitated to the basal ganglia.—Mr. VICTOR HORSLEY said that in man there was about the superior frontal convolution a secondary sulcus which was regarded as a landmark in the marginal convolution. In monkeys the same sulcus existed, and he had found experimentally that behind that sulcus the motor centres for the muscles of the trunk were situate. The absence of paralysis was perfectly accounted for in that the wound of the brain in Dr. Sainsbury's case was completely anterior to this motor region. With regard to the recovery of motor power in hemiplegia he dissented from the theory of Dr. Broadbent, and believed that the recovery of power was due to the removal of pressure by absorption of the blood-clot. He believed that there was double representation of parts of the body in one hemisphere, but the arm was probably represented singly in each hemisphere, and hence the difficulty with which the arm recovered in cases of hemiplegia. In these views he was not in accord with Hughlings Jackson.—Mr. HERBERT PAGE spoke of a case of injury to the brain in which the bullet lodged in the prefrontal region; there were no symptoms until the fifth day, when aphasia set in; death occurred on the ninth day, and the inflammation had by that time extended widely.—Mr. HULKE mentioned a case which had been reported by Mr. Lawson and in which a gunpowder accident had damaged the frontal region of the skull and brain without producing symptoms; the patient made a complete recovery.—Mr. ROSE, in reply, said he had detected no cerebro-spinal fluid in his case. He referred also to the celebrated "crowbar" case.

Dr. HALE WHITE read a paper on the Microscopic Examination of the Sympathetic System in Diabetes Mellitus. In all the cases some change was found, usually of a chronic inflammatory nature. Thus the note of one specimen of the thoracic sympathetic cord was that there was much increase of small cells, hiding almost completely the nerve fibres. There was great engorgement of the vessels, and also new growth of fibrous tissue. In this case the splanchnics showed the same change, whilst the semilunar ganglion presented great increase of interstitial fibrous tissue, abundance of new small cells in many places developing into fibrous tissue. The semilunar ganglion from the second case was almost the exact counterpart of this, whilst in the third case the changes although present were less marked. In the fourth case dark brown degenerative patches were to be seen scattered about the section, the vessels were so much dilated that they looked not unlike a cavernous structure and the tissue around the vessels was degenerate, and they contained many white blood-corpuscles, some of which might be seen to have wandered into the tissues. Inasmuch as sections of the sympathetic vary so much among themselves Dr. Hale White had examined over a hundred and fifty slides to familiarise himself with the normal appearance, and came to the conclusion that all these four cases of diabetes presented abnormal sympathetics. It was suggested that these cases showed that sometimes at least diabetes is due to

Digitized by Google

disease of the sympathetic, which belief was borne out by the numerous physiological experiments by which glycosuria was produced by acting on the vaso-motor sympathetic system. It could not be expected that lesion of the vaso-motor nerves should always produce glycosuria, for the area of vascular dilatation might be too extensive or the lesion might be irritative and not paralytic. In support of this view, as was pointed out, some of the other symptoms might be explained by supposing the disease to have affected the vaso-motor system—e.g., polyuria, thirst, red tongue, coma. In one or two cases contraction of the pupil and hyperidrosis unilateralis have been observed. Diabetes might be due to one of three causes:—First, affection of the vaso-motor nerves in some part of their course between the vaso-motor centre and the liver, as in the four cases here recorded. Secondly, affection of the vaso-motor centre itself, as seen in the cases in which glycosuria was due to cerebral lesion. Thirdly, affection of the vaso-motor centre reflexly, as in the cases of neuralgia, sciatica, &c., with glycosuria as recorded by Frerichs.—Mr. C. B. LOCKWOOD said that the anatomical relationships of the semilunar ganglia were different on the two sides of the body. Had both ganglia been examined? In injury of the frontal region of the brain glycosuria sometimes occurred.—Dr. HADDEN had examined portions of the brain, medulla, and semilunar ganglia as well as the sympathetic nerves going to the liver in some cases of diabetes. He found all these parts normal, and could not satisfy himself that the appearances were abnormal in Dr. White's specimens.—Dr. PYE SMITH thought no one could doubt that the specimens were abnormal.—Dr. HALE WHITE said that in one case both ganglia were examined and presented the same lesions. Frerichs gave two cases of disease of the trigeminus in which there was glycosuria.

The following card specimens were shown:—Mr. G. R. Turner: Congenital Tumour of the Perineum. Dr. Hale White: Congenital Malformation of Lung and a specimen of Patent Ductus Arteriosus. Mr. D'Arcy Power (for Dr. Mackinder): A Pouched or Duplicate Bladder. Mr. Rivington: A specimen of Osteitis of the Upper Part of the Tibia with Disease of Knee-joint.

CLINICAL SOCIETY OF LONDON.

Discussion on Charcot's Disease.

THE adjourned debate on this subject was resumed, but not concluded, at the meeting held on Dec. 12th, Sir Andrew Clark, President, in the chair. On the motion of the President, it was determined that an extra meeting should be held in order to finish the discussion, and the date fixed was Dec. 19th, which, however, as announced elsewhere, was subsequently changed to the 23rd.

Dr. DUCKWORTH read a *précis* of two letters which he had received from Professor Charcot. Two specimens sent by Charcot were specially referred to. One was from a cast of pied tabétique, and the other was the pelvis and the upper extremities of the femora of a case of locomotor ataxia. Charcot had not met with the joint disease apart from tabes dorsalis. He admitted that rheumatic arthritis may supervene in the course of tabes dorsalis, but that was another matter. Reference was made to the porosity and fragility of the bones. Dr. Duckworth repeated his conviction that in Charcot's disease we had a definite clinical condition determined by disease of the spinal cord or some part of the central nervous system.

Dr. MOXON proposed a vote of thanks to Professor Charcot; this was seconded by Mr. MORRANT BAKER, and carried by acclamation.

Dr. MOXON, in proposing the vote of thanks, professed much admiration for Charcot. Assuredly no connoisseur had ever brought so proud an imagination to his science, and no scientific imagination ever had a better power of observation subordinated to it. Without pretending to a Carlylese worship of a fact, yet he had great respect for facts. In reviewing the discussion he experienced an indefinite state of mind, which was uncomfortable to him. Referring to Sir James Paget's speech, he considered that he might beg, with Sir Andrew Clark, that Sir James would make more clear what it was that he meant. When he remembered the range of thought and accuracy of utterance which were at Sir James's disposal, he confessed to a certain degree of disappointment, and he was particularly sorry to find that herpes zoster had been dragged in. Herpes zoster was a narrow clinical puzzle, just as such substances as selenium, iridium, and rubidium were narrow chemical puzzles. He did not think that the turning on of herpes zoster could throw any possible light on Charcot's disease. He referred to a typical case of herpes zoster in which a medical man had told the patient that the disease at its beginning was a mixture of gout, neuralgia, and rheumatism. As far as he knew, Charcot's disease was extremely like rheumatic arthritis, and he fell in with the views of Mr. Hulke, and could see nothing peculiar in this so-called peculiar disease. He thought that the more vaguely he spoke the better it would suit the occasion. Charcot's disease seemed to him to be hopelessly indefinite, and whereas herpes zoster was definite, typical, and full of nerve from beginning to end, this so-called peculiar joint disease had no nervous phenomena at all. Sir James had failed to fit the case altogether. Looking at the line of indefiniteness which surrounded Charcot's disease and rheumatic arthritis, might it not be through our ignorance that they do coincide? So far he had dwelt on negative points, but he despised negativism, and would now advance a positive contribution. Locomotor ataxy has branches, and he did not think that Charcot's disease was a grafted branch. Eight years ago Westphal pointed out that in general paralysis of the insane the conditions of locomotor ataxy were present. This statement of Westphal's drove him to St. Luke's—as an observer,—and he also took with him a galvanic battery and several Guy's men. He found that a third of the general paralytics had the physical conditions of locomotor ataxy. Dr. Savage had found that the same holds good for Bethlem, and he had also Dr. Savage's permission to state that no case of Charcot's disease had occurred amongst the general paralytics. Might there not be some relation between this absence of disease of joint in cases which were paralysed and ataxic? He suggested that simple rheumatism might be changed into an exaggerated unrepresentative, irritative, severe, strange, and peculiar disease when occurring in cases of ataxia, and in illustration of his remarks he showed a specimen of the shoulder-joint of an ex-cabman who was thrown from his cab a year before his death. Here he thought that the constant jolting of the arms had led to the wearing away of the head of the humerus, and compared this jolting to a "locomotor ataxic action" on the shoulder-joint. He considered that this specimen was halfway to a Charcot's joint; there was no production of new bone about it. If half a Charcot's joint can be made by wobbling alone was it not possible that a whole one could arise as the result of wobbling when the nerves were in a diseased state. If careless and continued use could produce such changes, it was surely better to search for traceable causes. When he was demonstrator of anatomy he taught that the nerves going to a muscle also supplied the skin over that muscle on the side towards which motion was effected, and further that the joints were also supplied, generally on the side towards which motion takes place. There must be some meaning in that. It was a requisite of joint life that the moving agency should be duly checked. And if we took away this sensibility, this agency for checking movement, must we not measure that before we are told that there is a special disease? Common rheumatism after long experience of insensitive joint and spasmodic muscle might be turned into Charcot's disease. If the cabman had had an insensitive state of joint as well as the spasmodic action of muscles, he could not help thinking that the half Charcot's joint would have been a whole one. He confessed that the narration of the following case cost him pain. It was that of a case of perityphlitis in a man in whom there was a board-like hardness of the cæcal region, and it was desirable for the man's good that an examination should be made under chloroform in order that the hardness of muscular action might be got rid of. After returning to consciousness the man experienced the most intense agony, and died in nineteen hours from peritonitis, the result of rupture of the intestine. This case led him to consider the value of the protective agency of the motor parts of the body, and made him very recognitive of the degree in which ready sensitiveness helps a patient. These natural medicative powers being absent, he thought that an exaggerated irritative, severe, and strange disorder of joint might arise. The phenomenon of the discussion on Charcot's disease was not an isolated case. It was no new thing for a mysterious origin to be claimed for a local manifestation. Fifteen or twenty years ago the occurrence of auricular hæmatoma, or hæma-

Digitized by Google

toma auris, was assigned to a mysterious disorder of the nervous system. But the divine madness of youth, such as has been confessed to in the height of a scrimmage at football, may be accompanied by the formation of a bleb of blood in the external ear of a hæmatoma auris. A literary gentleman had informed him that the evidences of shrunken hæmatoma] auris were to be seen in statuary representing Greek boxers, so that this affection could not be looked upon as a development or twig of modern civilisation. There was a tendency, in the absence of proved direct causes, to appeal to the nervous system, as if the disease were a kind of special product. There used to be moderation in these views until the trophic nervous system was invented. By this system was meant a kind of Providence that supplied daily food to the joints, a sort of Secretary of State of the Joint Department; not that the nervous system actually found the material, but it should be remembered that Providence always uses means. Why should such a frightful, tenacious, unsparing catastrophe afflict one joint when it was no greater sinner than the rest? No one had shown that the nerves going to the diseased joints were diseased. (Sir Andrew Clark here referred Dr. Moxon to some observations by Charcot's pupils.) Until it were proved that the neural changes were primary and obvious, both destructive and irritative, he for one would not be content to allow that the nerves caused the arthritic affection. He had examined cervical ganglia in large numbers, and never made much out; there might be a little pinkness, a yellowness, or what not. Again, the fragile state of the bones used to be attributed to the state of the nervous system in the inhabitants of those vast hotels of not very critical guests. And recently a case of fracture of the ribs and sternum had been reported in the LANCET, and he dared say that the bones were soft. This fragility of bone became startling only when the conditions were mystic. The tendency to bring in the vague and general and to avoid measuring the force of the direct and measurable causes must be deprecated. So it was with the unilateral bedsore of cases of hemiplegia. He was not ready to admit the influence of trophic nerves in this connexion. Here there was tendency of the body to roll upon the paralysed side by the continuous action of the still active limbs. In this connexion Dr. Moxon referred to the manner in which the perforating arteries of the thigh were protected as they run under a tunnel of fibrous tissue, which in the contraction of the muscle was kept open so that the arteries were not constricted. It was the duty of a muscle to hold open its own arterial channels. When a muscle is paralysed the vascular supply suffers, and as the vessels of the gluteus maximus pass through the muscle before supplying the skin what was the wonder that the skin sloughed? The play of genius of M. Charcot showed itself in the introduction of the marvellous to explain clinical phenomena. He was reminded of a time ten years ago when one of his colleagues now practising gynæcology—a word, by the way, which etymologically seemed to imply the most ambitious of all the sciences with the doubtful exception of theology—drew his attention to a case of what others diagnose as hysteria. There was profound anæsthesia of one side, and he found his ambitious colleague hard at work with sovereigns and shillings producing what he believed was called a transference of total insensibility. He was not quite sure what it was all about, but it was very obscure. However, potato parings cut into circles seemed to be endowed with the virtues of the noble metals. He concluded by saying that no one had ever brought so proud an imagination to his science, and no scientific imagination ever had a better power of observation subordinated to it than had M. Charcot.

Mr. HENRY MORRIS said that after the witty and brilliant speech of Dr. Moxon's it would be tame for the Society to come down to the level of a simple matter of fact. He narrated two cases of Charcot's disease. One was that of a man admitted in 1877 to Middlesex Hospital for disease of the knee, which seemed to require amputation. The joint had the appearance of aggravated chronic rheumatic arthritis, but it had all the special characters of Charcot's disease. There was in addition a malignant tumour of the face which had been five times removed, and was in fact a rodent ulcer. The limb was put up in a Thomas's splint. Six years before being seen the man had been working in water, and then felt pain of a rheumatic character, which lasted twelve months before swelling of the joint occurred. At the end of six years the leg hung like a flail upon the thigh. The internal ligament of the knee was ossified. Eight weeks before death there was difficulty in speaking, and blood was vomited a few days before death. The case was one of long-standing Charcot's disease without ataxic symptoms, and improved under the rest obtained by means of the splint, though the movement continued to be free in many directions. The disease was of a rheumatic character, and he agreed with Mr. Hutchinson that the insensitive state of the joint largely contributed to the causation of the disease. The other case was that of a man with elephantiasis of one limb, and intestinal obstruction due to an enormously thickened volvulus, in which the sac-like omentum was greatly thickened, and which must have existed a very long time; the man died from the obstruction after having experienced severe sudden pain in the abdomen lasting but a short time. In this case the ankle had lost all its normal characters; the man walked on the inner border of the foot, and there were perforating ulcers on the great toes of each foot. The right foot had become diseased twenty-one years before, bone having been lost and suppuration set up. Fifteen years before the left ankle became affected, and the elephantoid condition of the skin had lasted ten years. At the autopsy there was a saucer-like cavity about the ankle, with thickening of bone around the tibia and fibula, which were firmly united; irregular thickening of the shafts of the bones also existed; the posterior tibial nerves of both sides were swollen, and sections made by Mr. Hudson showed changes in the nerves like those described by Messrs. Savory and Butlin; there was enormous thickening of the epineurium, but little of the perineurium, and some thickening of the endoneurium. The sensory fibres were almost absent. The painlessness of the disease, the long continuance, the profuse perspiration without ataxic symptoms were noteworthy features.

Mr. HERBERT PAGE spoke of the case of a man who had had severe gastric crises, lightning pains, and in whom the tarsal bones of one foot were disorganised, the other foot following suit soon after. (Clinical Trans. 1883) The feet were put up in plaster-of Paris and ankylosis obtained. The feet were extremely misshapen. There was little or no ataxia in the case. In August, 1884, there was a recurrence of the attack in one foot, the ankle and tarsal bones being involved. If this were an exacerbation of rheumatism it was strange that it should not have attacked the other foot. It was the clinical features on which Charcot established the disease as a wholly distinct malady. The wearing away of the bone is rapid, and not like a rheumatoid change in which friction might play a part. Further, in the case above mentioned other symptoms clearly referable to the nervous system were present, as, for example, the attacks of hæmaturia. Why should we not admit that irritative lesions of nerve trunks produced changes in the parts supplied wholly different from those alterations which might result from mere removal of nervous influence, as in cases of simple section of nerves? Further, in cases of irritative nerve lesion, as when a contractile scar irritated a nerve trunk, the changes induced at a distance ceased when the nerve was freed from the irritating scar tissue. And if lesions of nerve trunks could set up changes, why should not lesions of the central parts of the nervous system have the same influence? He felt sure that the pathology of acute bedsores was of this nature. With regard to the whole question, he thought that we were in a condition of what he termed individual belief. In his belief Charcot's disease was a distinctive affection of joints.

In reply to Dr. MOXON, Mr. PAGE said that there was no ataxy of gait, and that the recurrence of joint disease affected only one foot.

Dr. MOXON then inquired whether rheumatism was less capable of acting on one side than locomotor ataxy; was not ataxy always of both sides?

Dr. PYE SMITH said that there was no evidence to show that any disease was new. Cholera and diphtheria were not new, and cerebro-spinal insular sclerosis had only recently been recognised. With regard to the relation of Charcot's disease to osteo-arthritis, he said there was no adequate evidence for separating them. In osteo-arthritis there was great excess of bony growths, whilst in Charcot's disease there was a great deal of wasting of cartilage and bone, yet if a sufficient number of specimens were examined, more or less attempts at the production of new bone would be found. The age and duration of the disease allowed of the distinguishing of varieties in the large group of cases. A contrast was drawn between the rheumatoid changes in a young woman and those in an old man. Acute rheumatism was an entirely different disease. And yet occasionally cases of acute rheumatism exhibited changes in the phalanges like

Digitized by Google

those of osteo-arthritis. Brief mention was made of two such cases, both of which had valvular disease of the heart. Trophic nerves had now been allowed an existence by physiologists, though Schiff's early experiments and those of Donders were first interpreted otherwise. The evidence for the existence of trophic nerves was so strong that there could be no doubt on the matter. Mr. Hilton had observed how lesions of the hand waxed and waned with pressure on the ulnar nerve by an exostosis. Again, bedsores of rapid and violent production were best explained on the assumption of their existence. Zona followed the course of the nerves, yet nerve lesions could hardly have anything to do with Charcot's disease, seeing that the anterior roots were not involved in tabes dorsalis. The whole pathology of gout was so different from osteo-arthritis that confusion on this score ought to be impossible. Irish disease was almost a synonym for osteo-arthritis. Gout is almost unknown in Ireland and Vienna, so much so that when a specimen of gouty joint appeared it was long before the nature of the disease was recognised in Vienna. The fetlock of a horse sometimes showed an example of osteo-arthritis. Busk had discovered osteo-arthritic lesions in bones found at Gibraltar, which must have belonged to bears of the glacial period. And Flower had shown the cervical vertebræ of a porpoise with similar lesions. Syphilis certainly had nothing to do with these affections. Hutchinson had rescued the lesions of congenital syphilis from the group of scrofulous diseases. Dr. Pye Smith considered that tabes was not an absolutely fixed and definite entity. He differed from Dr. Wilks in believing that there was a real complex of symptoms which might justly be said to come under the wide category of tabes dorsalis. He concluded by referring to the dictum which said that investigation was to be preferred to speculative imagination.

MEDICAL SOCIETY OF LONDON.

Relapsing Pneumonia.

AN ordinary meeting of this Society was held on Monday last, Mr. Arthur Durham, President, in the chair.

Sir ANDREW CLARK read a paper on a case of Relapsing Pneumonia in an aged person, an abstract of which will be found on another page.

Dr. C. T. WILLIAMS said that he had always regarded acute croupous consolidation of the lungs, not as a local disease, and not exactly as an inflammation, but as a case of blood-poisoning. He put such cases in the class of fevers. He had seen somewhat similar cases, though the relapses were neither so frequent nor severe. Supporting treatment was all that was wanted.

Dr. SANSOM asked whether there was any history of the inhalation of vitiated air. He quoted a case in which there were rigors, with the accession of febrile symptoms and initial partial consolidation of the right upper lobe; delirium was very great indeed, and lasted a few days; the illness was an extremely rapid one. A few days later he found the patient with precisely the same symptoms, which ran almost exactly the same course. In both cases there were rusty sputa, but the patient had also severe hæmoptysis. Recovery took place by defervescence at the end of a week. He referred to another case of pharyngitis with febrile acumosis on alternate days for a week, in which a severe attack of consolidation of the lungs was passed through. The etiology of this case was as conclusive as anything could well be; there was a large crack in the soil pipe, from which sewer gas found its way into the bedroom of the patient; and, in fact, all the residents in the house suffered in some way or other.

Dr. DOUGLAS POWELL was a little disappointed that Sir Andrew had not given his explanation of the case. Had the patient been exposed to malarious influences? Recurrent thrombosis suggested itself as a method of explanation, but the clinical symptoms did not fit with this hypothesis. At the fag end of pneumonia, in some instances, the resolution seems to take place too fast, and an overdose of morbid material is taken into the circulation, and hectic phenomena produced. He described such phenomena many years ago.

Dr. ROGERS spoke of the case of a gentleman seventy years of age, who went through six relapses of pneumonia. Twelve years ago he had rheumatic fever with valvular affection. There was a history of gout in the family. He was attending the patient for rheumatic gout; a rigor set in, the temperature rose, and the signs of consolidation of the middle lobe of the left lung were made out. There was no cough and no expectoration. Delirium set in suddenly. There were frequent changes in the patient's state, very much as happened in Sir Andrew's case. He believed there was some poison at work in the system. Eczema broke out in the course of the case. There was something more than inflammation in pneumonia.

Dr. T. H. GREEN said he still felt somewhat in the dark as to the nature of the case under discussion. He considered that "pneumonia" was a general fever with a local manifestation in the lungs. He would separate Sir Andrew's case from those of acute pneumonia. It seemed to him that the case was more likely to be due to some septic influence.

Dr. SIMMS inquired into the family history of the case, especially as regards rheumatism and gout. The relapses at regular intervals suggested such an etiology. Cases had been recorded by Dr. Johnson, in which there was no expectoration, and in a case under his care there had been no expectoration whatever; these cases were probably of a gouty or rheumatic nature.

Dr. S. COUPLAND thought the case must be placed more in the category of septic pneumonia than anything else. With regard to the histological nature of pneumonia, he referred to the views of Hamilton of Aberdeen, who believed that pneumonia was not an inflammation, but was due to a profound circulatory disturbance. That view had not been accepted by the majority of histologists. The lung might be best compared to a serous membrane where there were fibrinous exudations in inflammation. An inflammatory change was almost solely a vascular change, and so where we had to do with congestion and rupture of vessels it was possible for the mind to perceive a distinction without a difference in the views which had been propounded respecting the histological nature of pneumonia. He himself preferred not to teach his pupils the view of Sir Andrew and Hamilton.

Sir ANDREW CLARK, in reply, said the expectoration was very minute in quantity. It was no rare thing for him to see cases without expectoration, and he ventured to say that one-third of the cases at the London Hospital had no expectoration. He thought that there was no evidence of cell proliferation or cell advancement, but as the whole aspect was one of regression, and, further, since there was a want of close organic union between the exudation and the alveolar wall, and no sign in the alveolus of any textural change, that he was justified in the views he held. The products of inflammation of the pleura were totally unlike those of pneumonia. Textural changes may be observed in pneumonia when the alveolar wall is excited to action by the presence of foreign material. He was quite familiar with the cases of relapsing pneumonia due to too rapid absorption from a resolving consolidation, as well as with those due to perityphlitis, pelvic cellulitis, or phlebitis. He believed that a malarial influence might have been at work in this case. Gout was also a possibility. He had seen at least a dozen such cases as the one recorded, and had made two post-mortem examinations which seemed conclusive of the presence of pneumonia. The intimate nature of disease could not be determined by anatomical alterations.

Mr. DURHAM showed the Cervical Cyst of a boy whom he had exhibited at the Society two weeks ago.

Dr. RADCLIFFE CROCKER showed a case of Gangrenous Ulceration of the Groin in a child; the disease began three weeks after the measles.

OPHTHALMOLOGICAL SOCIETY.

Unilateral Irido-Choroiditis.—Retinitis Albuminurica.—Vesicle of Cornea.—Hyphæmia.—Hysterical Deviation.—Cocaine.—Ophthalmic Models.

A MEETING of this Society was held on Dec. 11th, Mr. J. Hutchinson, F.R.S., President, in the chair.

Mr. MARCUS GUNN showed a child, aged eight years, the subject of Unilateral Choroiditis. Some years before this child's birth the mother had suffered from syphilis. Two years ago the child had a feverish attack, probably due to meningitis. Mr. Gunn found that there were numerous synechiæ in the right eye; the optic disc was occluded by a

Digitized by Google

dense light grey mass, with well-defined edges, which protruded forward into the vitreous; vessels could be traced over it. Stretching inwards from this structure was a narrow detachment of the retina, and another detachment was seen in the region of the macula. There were numerous patches of choroidal atrophy. In reply to the President, Mr. Gunn said that he considered the lesions to be due to congenital syphilis, but that he had difficulty in accounting for the condition of the vitreous.

Mr. HENRY EALES showed a case of Retinitis Albuminurica in the Left Eye only. The patient was a man aged twenty-five years, single, by occupation a striker. He first came to the Birmingham Eye Hospital on August 25th last, complaining of loss of sight in his left eye of three weeks standing, when in Mr. Eales' absence he was seen by the house-surgeon, who made a note that his right eye was normal while his left eye presented all the typical appearances of retinitis albuminurica, that the urine contained albumen in a small quantity and that he was a heavy beer drinker of seven years' standing. On September 1st Mr. Eales saw him and confirmed the above. On inquiry it was ascertained that on Saturday, August 2nd, being very drunk, he had a fall on some steps in which he twisted his left side. This pained him for a fortnight after so severely that he was unable to stand upright. His urine remained normal in appearance as far as he could tell, but on the following morning he noticed his sight dim, there being "a cloud over the upper part of his sight." He has never had scarlet fever, syphilis, or, in fact, any illness till the present. Having been treated as an in-patient, by frequent purgatives (mostly of elaterium), hot baths, and with liq. ferri perchlor. and digitalis as the principal medicines, the albuminuria and retinitis rapidly subsided—indeed for a time it was thought the albuminuria had quite disappeared, but careful investigation still showed albumen in slight traces in the urine about two hours after breakfast No casts have been found, possibly on account of not being looked for in the more acute stage of the affection. The retinitis was typical, the retina being covered by large milky opaque effusions, with a few hæmorrhages, the yellow spot and disc being especially affected. The right eye has never shown a sign of retinitis, even of the slightest kind. The present state is as follows:—The right eye was normal; in the left eye the disc was white and atrophied, and its margin blurred; the retinal arteries were reduced to threads, and several glistening dots were present in the retina all round the macula like that seen after typical retinitis albuminurica. The urine showed a trace of albumen after breakfast, but at no other time.

Mr. MCHARDY showed a drawing of a case of Unilocular Retinitis in a patient suffering from Albuminuria. The patient had been under the care of Dr. G. Johnson, and the case was shown at the International Medical Congress in 1881. He referred to another reported case of unilocular albuminuric retinitis, in which also there was but one kidney.—Dr. STEPHEN MACKENZIE related a case which had been placed under the care of Dr. Hughlings Jackson on account of a disease believed to be albuminuric retinitis; the presence of albuminuria appeared to confirm the diagnosis, but the optic nerves were more swollen than is usually the case in albuminuric retinitis, and had rather the appearance seen in tumour. The patient ultimately had convulsions, followed by coma and death. The necropsy revealed tubercular meningitis. There was only one kidney, and this was not diseased. He believed it to be impossible, in certain cases, to decide from the ophthalmoscopic appearances whether the lesion was albuminuric retinitis or whether it was a condition which sometimes occurred in connexion with brain disease. Recently Mr. Morton had referred a case to him where the appearances resembled those of albuminuric retinitis. The necropsy showed a tumour of the corpus striatum and optic thalamus of one side. Having these facts in view, and looking at the whole history of the case, he was inclined to suggest the presence of some coarse intracranial lesion in Mr. Eales's case. It was known that in cerebral tumour the optic neuritis was not unfrequently unilateral in the early stages of the case at least.—Mr. NETTLESHIP considered that the patches in the choroid were not the result of retinitis; he doubted whether the patches were coincident in time with the papilloneuritis, and thought, on the contrary, that they were probably of longer standing. The condition of the papilla pointed to the occurrence of thrombosis as not improbably the cause of the lesions of the fundus oculi. He would suggest that there was arterial thrombosis in an eye which had previously had some choroidal disease leading to atrophy.—Mr. EALES, in reply, said that the distribution and mode of development of the disease appeared to him to be incompatible with the explanation offered by Mr. Nettleship.

Mr. ANDERSON CRITCHETT and Mr. JULER showed a case of large vesicle of the cornea; the disease had existed for about five months. The vesicle had been about four millimetres in diameter at its base, but had recently burst. The chief symptoms were photophobia, lacrymation, and pain. The eye had previously been quite sound.

Dr. W. A. BRAILEY showed a case of Hyphæmia secondary to some deeply seated intra-ocular change; the prominent signs were double irido-cyclitis, with hæmorrhage into the anterior chamber, and great variation in the tension. The case was of interest owing to the obscurity which surrounded its mode of origin. There was no history of gout.—The PRESIDENT observed that slowly progressive iritis, with hæmorrhages into the anterior chamber and into the vitreous, generally occurred only in persons with a gouty history.—Mr. NETTLESHIP suggested that the case would perhaps fall into the group to which the term idiopathic phthsis bulbi had been applied; there were rapid variations in tension in this disease.—Dr. BRAILEY pointed out that the case differed from idiopathic phthisis bulbi in every respect except the variation in tension.

A case of conjugate deviation of the eyes to the right in a hysterical woman aged twenty-five was shown.

Mr. NETTLESHIP read a short paper on Cocaine in Ophthalmic Practice, which had been communicated to him by Mr. Simeon Snell, and the gist of which will be found in a letter from that gentleman published in our last number. Mr. Nettleship then read an elaborate paper on this subject. He had operated on about seventy eyes under the influence of cocaine since Oct. 10th, on which day six eyes were so dealt with. The number of eyes so operated on were as follows:—Extraction of cataract, with iridectomy, 12; extraction of cataract after preliminary iridectomy, 4; extraction of soft cataract through small incision without iridectomy, 4; iridectomies for various purposes, 16; conical cornea (apex excised), 1; discission, 8; iridotomy, 2; scraping corneal ulcers, 2; tenotomy, 17. It was used in several other operations (chiefly tenotomies), and almost daily for several weeks in cases of foreign body on the cornea. The preparations used were a 2 per cent. watery solution, a 2·5 per cent. solution in vaseline and in castor oil, occasionally a 4 per cent. watery solution, and of late usually gelatine disc (made for the writer by Savory and Moore about the middle of October), each disc containing $\frac{1}{10}$ of a grain of cocaine hydrochlorate. These always caused complete anæsthesia of the cornea and conjuctiva of healthy (that is, non-inflamed) eyes; but the iris had never been completely anæsthetic in any of the operations involving iridectomy, even after frequently repeated applications; he doubted, indeed, whether the sensibility of the iris was lowered at all in any of the cases. In one preliminary iredectomy the patient became so unruly when the iris was grasped that the operation had to be completed under chloroform, and with the other patients some difficulty was experienced at the iridectomy stage, although the operations were satisfactorily finished without general anæsthesia. In tenotomy there was sometimes slight pain, when the parts were put on the stretch by the hook and scissors. But with the exception of the iridectomy mentioned above, the operations had almost invariably been completed without a hitch, with next to no discomfort to the patient, and with no bad after-effects. Had cocaine not been in use, ether or chloroform would have been given to about one-half of the patients referred to. Cocaine was used prior to the application of the actual cautery to granular lids on several occasions with partial success; in a case of cauliflower warts about the inner canthus, and in a case of lupus on the skin of the lower lid, with little or no success. Cocaine greatly relieved the photophobia in several cases of corneal ulcer. When the ciliary region was much congested, it remained sensitive to deep pressure, though the conjunctiva seemed anæsthetic to light pressure, and the cornea completely so. The mydriatic effect was often less marked in inflamed than in healthy eyes, and repeated applications to congested eyes had not produced any decided blanching. A single application to the healthy eye caused complete anæsthesia in two or three minutes; about four minutes later this began to diminish, and had entirely passed off about twenty minutes from the time of application. Retraction of the upper lid began in

Digitized by Google

four or five minutes, and lasted about half an hour; during the same time well-marked blanching of the surface of the globe occurred. Mydriasis began in three to ten minutes, was at its maximum ten to fifteen minutes later, and lasted in all at least twelve hours. The reflex and associated actions of the pupil were present throughout. Accommodation, though scarcely affected by one application, was almost completely paralysed, but for a very short time, by repeated applications. A single drop of eserine solution acted as fully and quickly as if no cocaine had been used. Probably the retraction of the upper lid, whitening of the eyeball, and mydriasis were caused by spasm of muscular fibres innervated by the sympathetic. The very fleeting cycloplegia caused by the repeated use of the drug might be due to ischæmia of the ciliary muscle from spasm of its nutrient arteries.

Mr. ARTHUR BENSON of Dublin contributed a paper on the same subject. The author found that the specimen of cocaine with which his previous experiments had been conducted was contaminated, probably with eserine. Hence the subsequent contraction of the pupil, &c. This result did not occur when the pure drug was used, but the pupil remained dilated for several hours. The most minute trace of eserine counteracted the dilatation. He found in experimenting on himself that the anæsthesia produced reached its maximum in two or three minutes, and was extremely local; he could, by applying a small quantity, produce anæsthesia of one half of his cornea and conjunctiva, whilst the other half retained perfect sensation. The degree of anæsthesia depended, within limits, upon the amount of the drug employed; repeated applications of a 2 per cent. solution produced almost total anæsthesia of the cornea and conjunctiva, so that the removal of foreign bodies and other operations could be performed painlessly. The sensibility of the iris seemed to be only slightly, if at all, diminished. He had applied it on the tongue and lips without marked result, a slight dulness of sensation alone being produced. In cases of photophobia he had used it with marked benefit (keratitis and conjunctivitis), and considered it of great value in facilitating the examination of such cases, as well as from a therapeutic point of view. In normal eyes it usually produced an increase of tension amounting to +1 within from half to one hour, the tension falling before the dilatation ceased. He had not tested its effect upon the tension of diseased eyes. He had removed an aural polypus, having applied cocaine to the ear, with apparently good results. He was certain that the drug when used pure and in abundance would prove one of the most valuable ever discovered. Its action being so local, and the duration of the anæsthesia so limited, it should be used abundantly, and a very short time before the operation. Owing to the lateness of the hour there was no discussion on these papers.

The sitting was prolonged for a short time to allow Mr. PRIESTLEY SMITH to demonstrate models illustrating the following points:—1. Hypermetropia and myopia; a diagrammatic section in two parts, the one sliding upon the other. 2. The condition of the retinal picture in emmetropia, hypermetropia, and myopia, with and without accommodation, and with and without glasses; a spherical wooden model capable of elongation, and with a movable lens. 3. The same conditions by a different arrangement, and to demonstrate the fundus image-test. 4. Astigmatism; a "cornea" of indiarubber cut from the side of a large ball. 5. The mechanism of accommodation; a thin elastic steel band curved to the proper shape to represent the lens in section. The suspensory ligament was represented by spiral steel springs; the ciliary muscles by ribbons, which could be pulled upon when it was desired to illustrate the action of the ciliary muscles. 6. The causation of diplopia, and its correction by prisms; two cardboard cylinders mounted on a vertical axis, with a convex lens in front, and an aperture covered with thin paper behind. At the yellow spot region the paper was made more transparent by a drop of paraffin; at the fixation-point was a lighted candle. The relation between deviation of the cornea and the apparent deviations of the image in paralysis of the sixth nerve, and in other deviations of the eye, could be demonstrated, as well as the effect of prisms. Mr. Priestley Smith also exhibited a simple artificial eye, and an apparatus for demonstrating operations on pigs' eyes, which consisted of two short cylindrical pillars with cupped extremities, over which tubular caps slided, and held the eyes which lay in the cups tense.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, Dec. 3rd, Henry Gervis, M.D., President, in the chair.

The following specimens were shown:—Dr. Walter (Manchester): Fibrous Tumour of Uterus removed by Operation. Dr. Horrocks: Two-headed Fœtus. Dr. Godson: Fibrous Polypus. Dr. Champneys: Ruptured Uterus.

Discussion on Dr. Graily Hewitt's paper on uncontrollable vomiting in pregnancy, adjourned from the November meeting. Drs. Champneys and Galabin spoke at the November meeting, but the whole discussion is given below.

Dr. CHAMPNEYS observed that many of Dr. Hewitt's anticipations of probable objections amounted to a declaration that, in spite of them all, he believed his own theory. Anteflexion or anteversion is found in 80 per cent. of all cases of early pregnancy. No attempt has been made to show the difference as regards vomiting between those whose uteri are "displaced" and the small minority in which they are not displaced. In the puerperal state anteversion and anteflexion are at least as common. Here is a large uterus, full of blood, anteflexed, but where is the vomiting? Again, it has been assumed that anteflexion is a position of constraint. Here are these women lying on their backs, and yet the uterus is persistently anteflexed. It has never been proved that flexion as flexion ever disturbs the circulation in the uterus. If, however, we look for a typical condition of flexion with pressure, we find it in the case of the retroverted gravid uterus. Here we may have acute flexion with incarceration, either of which, on Dr. Hewitt's theory, is sufficient to cause vomiting. But where is the vomiting? Flexions have been proved to be very common in women, whether well or ill, and association, without severe sifting, proves nothing. The sudden cessation of vomiting recorded in some of the cases is a well-known character of this vomiting, and is a precarious foundation for theories. The cases themselves require more details as to other possible causes of vomiting, such as albuminuria, jaundice, constipation, &c.

Dr. GALABIN said that anteflexion was so common in early pregnancy that it was one of its best diagnostic signs. If it were the cause of vomiting, a pessary should cure the vomiting. Not one of the cases related was cured by this means. In backward displacement relief followed reposition oftener in Dr. Hewitt's cases. Excessive vomiting was plainly only an extreme degree of the common vomiting of pregnancy. Tension must be an important element, witness the cessation of vomiting if the ovum dies, and the excessive vomiting associated with hydatid mole. When the nervous system is hyperæsthetic, some morbid condition of the uterus, such as inflammation, induration, and grave displacement, such as retroversion, especially with incarceration, might produce excessive vomiting. Dr. Hewitt's theory did not explain the relief which he had several times seen follow dilatation of the cervix. The *modus operandi* of this procedure was hard to explain, but it might be connected with overstretching the nerves or rupturing some of the fibres about the os internum, which is a special seat of reflex action in labour. Incarceration of an anteverted or anteflexed uterus in early pregnancy was to him inconceivable apart from adhesions.

Dr. BARNES said that excessive vomiting in pregnancy was an instance of a physiological process passing the healthy boundary. The physiological basis is vascular and nervous tension peculiar to pregnancy. Vomiting is a safety valve for nervous energy, and a safeguard against nervous seizures, such as eclampsia. Vomiting is a sort of physiological convulsion, and so is labour itself. After delivery the tension ceases, and the liability to vomiting also. The exciting cause of the vomiting of pregnancy is usually in the uterus itself. The fact of the vomiting occurring as soon as the patient gets up may be partly explained by increased flexion, partly also by Bretonneau's theory of rapid distension of the uterine fibres under increased hydraulic pressure of the blood from the erect position when the nervous centres are most excitable after rest, and the inhibitory force weakest from fasting. Since flexion remains for the rest of the day, however, flexion is not sufficient. Vomiting later in pregnancy, which is the severer form, is kept up by starvation when once started, degraded blood increases the nervous irritability, and a vicious circle is formed. Albuminuria is a further evidence of toxæmia, and hiccough is a form of convulsion. The vomiting seen in obstructive dysmenorrhœa

Digitized by Google

is analogous. The solution is not to be sought in any one factor, but nervous and vascular tension underlie the whole question.

Dr. BRAXTON HICKS said the term "severe" was too vague, and he had never seen uncontrollable vomiting. The vomiting of pregnancy was so variable that severe vomiting could not be considered apart from the vomiting which might be called natural. When the pulse rose emaciation commenced, and when the tongue became red and the epigastrium tender, the case became urgent. He had never seen a case which had not yielded to remedies. With regard to the cause of vomiting, he agreed in many points with the previous speaker. Since Dr. Graily Hewitt's first paper he had examined all cases carefully, and he had never found any displacement or other local disturbance requiring mechanical treatment, nor had he ever failed to carry his patient safely to full time by the persistent use of remedies, especially opiates, given perseveringly until some portion was retained by the stomach, and the system was calmed. The nerves of the mucous membrane of the stomach became irritated, and after a time formed a centre of disturbance, after the manner seen in other parts. By the administration of opiates by the mouth these nerve ends were soothed, and consequent benefit secured.

Dr. MATTHEWS DUNCAN knew no controllable vomiting of pregnancy. Medicines might do some good, and perhaps in some cases stop it. This he did not deny, but everyone in practice knew that the vomiting was practically uncontrollable. He placed most reliance on atropia in the common variety of vomiting when excessive. The vomiting of pregnancy was of course stopped by emptying the uterus; that was not to control it nor really to stop it; that was to stop the pregnancy. He recognised, meantime, only two kinds of vomiting of pregnancy: the ordinary, natural, physiological; and the pernicious, uncontrollable — very dangerous. The former generally ceased about mid-pregnancy, but it might go on longer, be excessive, and induce emaciation. He was not quite certain that it ever ended fatally. The pernicious kind had been the subject of several recent memoirs, and was often fatal, rapidly fatal; it might begin at any period of pregnancy, and run its course slowly or more quickly; and till our new knowledge of this kind was used in the investigation of all cases, he would not admit that a fatal result came from the ordinary or physiological kind, even though very severe. The pernicious kind was no doubt induced by pregnancy, and in it we had degeneration of organs, granular, fatty, or inflammatory. Cases often presented all the characters of icterus gravis, but they varied much from the apparently simple cases of fatty degeneration of Hecker, Grainger Stewart, and others, to cases with symptoms more or less like those of Bright's disease or of yellow atrophy of the liver. They presented great prostration, often bleedings, often albuminuria, more or less considerable, also often bile in the urine. Sugar even had been observed. Such cases were not always fatal. He was disposed to regard this pernicious vomiting as certainly sometimes passing off after delivery, or perhaps even before it. It often led to the death of the fœtus. He knew of no remedy but emptying the uterus.

Dr. PLAYFAIR said that we are all apt to ride our hobbies too hard, but, in this respect, Dr. Hewitt carried off the palm with ease. Indeed, with perfect good faith, he fitted his facts to suit his theory. In many of Horwitz's cases there were conditions which might quite account for the vomiting, such as perimetric adhesion, tumour, parenchymatous metritis, and other inflammatory conditions. All these Dr. Hewitt calmly puts aside as beside the question, and points to a slight deviation as the cause of the vomiting. The plainest of all facts about the vomiting of pregnancy is that it is a neurosis of an intense degree, and only one of many neuroses accompanying pregnancy, and also associated with many forms of pelvic disease, such as inflammation and dysmenorrhœa. All these differ only in degree from the vomiting of pregnancy. It was observed long ago by Dr. Bedford of New York that when there was no vomiting in pregnancy some other and often more distressing form of neurosis, such as fainting and palpitation, was apt to be present. He therefore used actually to prescribe ipecacuanha as an emetic, and, Dr. Playfair thought, with much justice. In every case of intractable vomiting we should endeavour to find out the special form of irritation. There is much to be said about the risk of the indiscriminate use of pessaries and of cervical dilatation during pregnancy; but, above all things, it is necessary to take a broad scientific view of the whole question, and not to adhere to any exclusive theory, such as that advocated by Dr. Hewitt, to the overlooking of the concomitant conditions of which he makes so light.

Dr. CLEVELAND believed that the opinion of the Society was, on the whole, that the relation of the ascertainable condition of the uterus with, at all events, the less severe forms of vomiting could not be regarded in the light of cause and effect. Pregnancy disturbs the nervous equilibrium, and some women suffer from toothache, in others from a grave neurosis (may be) of the pneumogastric nerve (vomiting). His special object was to point out the danger to life from prolonged and excessive vomiting in pregnancy, and to inquire what is the probable mode of death Is it not failure of the heart's action, and if so, as one of the means of averting the tendency to death, ought we not to lay stress on the necessity of rest in the recumbent position? He related a case of violent vomiting in which death ensued on the patient's getting out of bed contrary to strict injunctions. Post mortem the heart was found somewhat dilated, the liver large and congested. The uterus was pregnant about ten weeks.

Dr. MURRAY was not inclined to believe that in pernicious vomiting other organs are implicated, for if so, why does the vomiting sometimes cease when the cervix is dilated? He had recently seen a case where this treatment stopped the vomiting for some days, but the patient died exhausted after expelling the uterine contents. There was no displacement of any kind. He thought that after a fair trial of remedies early interference with the pregnancy was best for the patient.

Dr. WYNN WILLIAMS did not find that flexion of the uterus, apart from adhesions, was associated with severe vomiting in pregnancy. Neurosis would account for great sickness. The only two deaths he had seen had been in alcoholic patients with liver disease. In a case of severe vomiting he had advised the passage of a sound just within and around the os uteri, and the vomiting had ceased.

Dr. BANTOCK had never met with a case of uncontrollable vomiting. He thought Dr. Hewitt's theory too one-sided. The apparent state of anteflexion in early pregnancy is not properly flexion at all, but a condition produced by change in the size of the organ as it grows and expands, the apparent flexion increasing as pregnancy advances. Therefore, the ordinary teaching that anteflexion is usual in early pregnancy is utterly wrong. He thought the cause of the vomiting was irritability of the uterine body, especially about the os internum. This is illustrated by the vomiting which accompanies artificial dilatation of the os internum (though not of the os externum), and also the normal dilatation of the os internum during labour. He could understand the possibility of increased tension of the fibres about the os internum in retroversion and retroflexion, but not in anteflexion, and still less in anteversion.

Dr. HEYWOOD SMITH said that the uterus of early pregnancy was best described as antecurved. He had a case in which vomiting had persisted to within seven days of confinement, but there was probably a small fibroid as well as ovaritis, and another case was probably due to cervicitis. He thought the fact that vomiting often began on waking and before getting up spoke against Dr. Barnes's explanation, and in favour of the waking up of the uterus and its renewed energy acting on an empty stomach.

Dr. GRAILY HEWITT said the paper stated that there were two factors in the vomiting: (1) altered position or incarceration; (2) induration of tissue near the os internum. Dr. Galabin said that the therapeutic test—viz., by the elevation of the uterus—spoke against the theory, but in five out of twenty-seven typical cases the sickness was cured by elevating and replacing the uterus, and in two others it was at once relieved for a time, the uterus not being maintained in position. Five other cases of severe sickness were cured by postural treatment, rest, and measures calculated to prevent impaction. Uterine sickness, apart from pregnancy, might even lead to vomiting of blood. He did not consider the frequent occurrence of degeneration of organs in pregnancy proved Dr. Playfair had made similar remarks to those made to-night, as to "riding a hobby," some few years ago, at a discussion of a former paper of Dr. Hewitt's, but a year or two later he stated that he had changed his mind since reading Dr. Hewitt's book. He hoped for a similar revulsion of feeling in the present instance. With regard to the criticisms on his cases, he had collected all the illustrative cases he could find, whatever their import. Vomiting after the

Digitized by Google

middle of pregnancy was probably due to continued distension and growth of the uterus acting on the indurated tissues near the os internum.

HARVEIAN SOCIETY OF LONDON.

A MEETING of this Society was held on Nov. 6th, Mr. H. Power, M.B. Lond., F.R.C.S., Vice-President, in the chair.

CLINICAL EVENING.

Dr. SYDNEY PHILLIPS showed a boy aged nine the subject of Movable Kidney. He had a lobulated elastic mass, situated chiefly in the umbilical and left lumbar regions, the upper edge of the mass reaching halfway between the ensiform cartilage and umbilicus, the lower edge halfway between the latter and Poupart's ligament. The tumour could be pushed downwards as far as Poupart's ligament, and was movable to a less extent in other directions. There was a marked hollowness and concavity in its left lumbar aspect. The tumour had been noticed after an attack of whooping-cough, when the boy was seven months old; it had gradually increased from the size of a pigeon's egg to its present dimensions, but for the last two years had not altered. During a period of observation of eighteen months his urine had been normal, and there had never been hæmaturia. The boy's health had been fair, but he had suffered from paroxysmal attacks of pain about the tumour. Dr. Phillips believed the tumour to be a displaced kidney which had undergone some change, possibly cystic, accounting for its increased size. It was not a double kidney, as the right kidney could be felt in the normal position.—Dr. STEPHEN MACKENZIE briefly discussed the case, and pointed out that the tumour was not typically kidney-shaped, and that the abdominal walls were not abnormally lax. These were important reasons for doubting that the case was one of movable kidney.—Dr. CHAMPNEYS considered that diagnosis in a case such as this should be based upon a process of exclusion. Had the patient been a female the existence of a dermoid cyst rising from the pelvis might have been strongly suspected. Against the hypothesis that this was an instance of movable kidney the following facts might be urged:—(1) As pointed out by Landau, the subjects were generally adults; (2) they were most commonly women; (3) in a large majority of cases a movable kidney was situated on the right side. The supposition of malignant disease was set aside by the long history of the tumour, which was first observed at the age of seven months. The complication of strangulation was negatived by the observation that for a long period the size had remained constant. With regard to the mobility of the mass, Dr. Champneys had noticed that the centre of movement appeared to coincide with the summit of the iliac crest, or, in other words, with a point perceptibly below the axis of the normal kidney. The final inference remained that this was a solitary, and, therefore, a hypertrophic kidney, and that it was slightly displaced, although not an instance of the malposition known as horseshoe kidney, which was the result of a congenital blending of both organs.—Mr. GANT, in commenting upon the case, gave his reasons for believing that its nature was an open question of diagnosis.—Mr. JOHN MORGAN remarked that he had not long ago had a boy under his care who presented a very similar tumour in the abdomen.

Dr. STEPHEN MACKENZIE narrated two cases of Lichen Planus in which the eruption was distributed along the course of cutaneous nerves, and remarked on the influence of the nervous system in the disposition of cutaneous eruptions. The first case was that of a woman in whom lichen planus was arranged round one-half of the back and abdomen in beltform, like herpes zoster, for which the eruption had been mistaken. Later the eruption became generalised. There was intense itching of the skin, and white patches on the buccal mucous membrane. In the second case, also that of a woman, the eruption was confined to a tract down the inside of one arm corresponding with the internal cutaneous and ulnar nerves, with intense itching in the area of eruption. Dr. Mackenzie proceeded to point out that these cases were deviations from the ordinary type of lichen planus, which was characterised usually by marked symmetry. He next drew attention to other cutaneous diseases which were distributed along the course of nerves, as herpes zoster, morphœa, neuropathic, papillomata, purpura, &c. He next considered the anatomical evidence explaining such neurotic eruptions. He then dealt with the significance of such eruptions, indicating his belief that the local lesions of the nervous centres merely determined the localised eruption, and that there was some other factor which decided its nature.—Mr. MALCOLM MORRIS said that cases of localised lichen planus like zoster were very rare. He referred to a communication in the *New York Medical Record* by Dr. Robinson, in which lichen planus and lichen ruber were described as two diseases, the former being the most localised. Mr. Morris thought, on the whole, that lichen planus was probably neurotic, and not a blood disease, as it often developed in persons who were severely depressed.—Dr. COLCOTT FOX remarked that modern researches had accumulated a mass of evidence to show that the nervous system played a very prominent part in the evolution of skin diseases, either directly through trophic nerves or through the agency of the vaso-motor system. From anatomical considerations it was evident that if a morbid influence was exercised through the vaso-motor nerves, the areas occupied by the eruption would correspond with the areas of blood-supply. It was difficult to resist the conclusion that the corymbose patches of eruption seen in a great many affections of the skin were thus caused. It was still more impossible to resist the conclusion that the patches of shingles were developed on the trajectory of a nerve, and, indeed, this had been placed on sure ground. From the mass of evidence to hand he might point to the evidence of nævi, both blood-vascular and papillary, in relation to nerve distribution.—Dr. STEPHEN MACKENZIE replied.

Mr. JOHN H. MORGAN narrated cases of Painful Mamma in Young Girls. A well-made girl, aged eleven and a half, had suffered from severe pain in the left mamma for some time, which had become more acute lately. The gland was very little enlarged and showed no symptoms of inflammation, but was the seat of great pain and was very tender to the touch. The pain was continuous, with exacerbations. There was no history of injury. The catamenia had not appeared. Shortly afterwards the right mamma became affected in an exactly identical manner. Neither local nor general treatment afforded relief. After some weeks the pain began to intermit, and at length gradually disappeared. Notes were read of six other similar cases, in five of which the left and in one the right mamma was the seat of pain. Mr. H. POWER referred to an article by Erb, dealing with this subject, in a volume of Ziemssen's Cyclopædia, which he had translated.—Mr. GANT alluded to a chapter in his own work on Surgery. This painful affection presented four well-marked characters:—(1) Hyperæsthesia, (2) wide distribution, and (3) superficial nature of the pain, (4) paroxysmal exacerbation. It might be looked upon as a pseudo-mastitis. In many cases it was probably the outcome of depraved habits. — Dr. CLEVELAND, believing in the neuralgic character of the pain, suggested that the hypodermic use of morphia might be expected to yield the same relief as in other neuralgiæ.

A new Antiseptic Vaporiser and an improved Surgical Syringe were exhibited by Mr. R. F. BENHAM.

Dr. AMAND ROUTH read details of five cases of Retroversion of the Gravid Uterus, two of which when first seen were complicated with resulting retention of urine; the bladder in these cases exactly simulating the objective signs of unilocular ovarian cyst. Seventy ounces of urine in the one case and fifty ounces in the other were drawn off. Reduction was easily effected in all the cases without subsequent abortion occurring, and with immediate relief of the symptoms.—Dr. CHAMPNEYS remarked that whereas in general outline cases such as those described were made up of combined flexion and impaction, none of the symptoms special to flexion or to impaction were present. Sometimes considerable difficulty was experienced in replacing the uterus; in such cases the pressure of water or of air was a valuable means of treatment. Dr. Champneys referred to a case recently seen by him in which an indiarubber bag was introduced into the rectum and distended with water under a pressure of four feet, with excellent results.

THE HOUSING OF THE WORKING CLASSES.—The Royal Commission on this subject at the conclusion of their fifty-first meeting adjourned on the 12th inst. until February 20th. It is hoped that the report relating to England and Wales will be presented to Her Majesty before Easter, and there will then remain the inquiry into the position as regards house accommodation of the working classes in Scotland and Ireland.

Reviews and Notices of Books.

La Gymnastique. By A. COLLINEAU, M.D. Pp. 824. Paris: J. B. Baillière et Fils. 1884.

THIS comprehensive treatise on gymnastics comes in good time to show that the education of muscle rests upon a scientific basis as sound as that of mental culture, and should occupy a place not less essential, if less pretentious, in every school curriculum, and in the daily duty of every life. The definition quoted from Dr. Hillairet, that "gymnastics is the science of movement, and has for its object the regular development of the whole body, the proportionate increase of all its forces," gives promise of a liberality and insight in the execution of the work which closer examination shows are not wanting. An interesting preamble on the history of such organised movement in past epochs and among rude as well as civilised peoples is followed by several chapters which describe with brevity, but with detailed exactness, the known facts of anatomy and physiology, for on these alone, as Dr. Collineau observes, any successful system of muscular exercise must be founded. Experimental proof is adduced in reference to the more important questions discussed, as for instance the results obtained by MM. Chassaignac and Dally and by M. François Frank, as to the effect of exertion on the respiratory and circulatory functions. If there is a fault in this direction it is that extracts from authorities are frequently interpolated when a mere *précis* might have sufficed for the ordinary student. Here, as throughout the book, diagrams are numerous, and are clearly and correctly executed. The general rules as to gymnastic exercise form a series of sensible preliminary observations, most of which are already recognised in practice. For children under eight years games are wisely preferred to any artificial method, and all are recommended to employ their powers with energy but not to exhaustion, and to proceed leisurely from lower to higher developments of force.

The author divides his subject into two sections: (1) the practice of exercises natural to the body, and (2) the use of artificial appliances. Before going into details, however, he has some pertinent suggestions on the effects of malpositions in school and on the causes which produce them. Spinal curvatures from faulty attitudes in reading and writing, and from the adoption of a constrained carriage in walking, are particularly noticed. The *rationale* of such curvatures consists in the irregular and unequal action of the muscles of the trunk combined with unequal distribution of the body-weight; and the remedies suggested are shorter writing time, the use of seats and desks at which a child can sit and work without twisting the trunk, and, lastly, the free and regular practice of simple gymnastics. A variety of these is described, forming collectively a kind of school-drill, and including many useful movements designed to educate and strengthen successively the muscles of the head, limbs, and body. Among many other practical hints it is noteworthy that a broad and low heel is insisted on as an essential for a good walking boot. Elaborate directions as to length of journey, pace, alternations of rest, and the like, are carefully detailed. Attention is drawn to the risk of inflammation of epiphyses and of heart-strain from over-walking in childhood. The bent legs and "pulled arm" which result from premature walking in infancy are mentioned, and a suitable caution enjoined. Running, jumping, dancing, and various balancing exercises receive due comment and illustration. The education of the muscles of phonation has a section devoted to itself. The passages relating to distinctness of speech and the pathology and treatment of stammering are worthy of perusal. There is probably no more important subject under treatment in this work than that of swimming. It is, on the whole, well treated. It seems to us, however, that rather too much is made of various contrivances for teaching the necessary movements on land. No cradle apparatus can possibly give a man any but a very theoretical idea of the way to swim. Such artificial aids have doubtless a certain value as means of muscular exercise, but for our own part we should have preferred to find a large part of the space which they occupy in this work devoted to the consideration of the cause, prevention, and treatment of cramp, a subject which hardly receives sufficient elucidation. Riding is well treated of. Its stimulant effect upon the skin, respiratory and circulatory organs, its fitness or unfitness in different morbid states, are stated at length.

The chapter on games cannot fail to interest an English reader, although his own familiar national pastimes are freely and at times not quite justly criticised, as when cricket itself is accused of sometimes stimulating "brutalité." Dr. Collineau maintains with much good sense that games are as necessary for elder as for younger pupils, and complains that this fact is often lost sight of when a youth is pushed blindly forward in some groove of mental culture without reference to his physical needs or the development of his originality. A number of suitable games and other amusements are passed in review, from cricket, hammer- and stone-throwing, to battledore and shuttlecock, which Dr. Collineau regards as specially adapted to the requirements of growing girls. Lawn-tennis he would reserve to the male sex. Here we think he shows excessive carefulness. His desire is to make not strong, but supple and graceful women. It is manifest that the combination of vigour with grace would form a yet higher type, and girls, we think, may fairly be allowed in most cases to follow their own fancy in the choice of their exercises, and should be limited not so much by conventional restraints as by the measure of their physical capacity. The chapters devoted to gymnastics proper, or those exercises which entail the use of special apparatus, are interesting and instructive.

The association of hydropathy with gymnastics is a noteworthy feature of this book. A bath or douche of water at 12°–16° C. is used by the pupil for from two to four minutes immediately after ceasing his exertions. After this again he rubs himself well with a dry towel, runs a short race, has a second dry rub, and dresses. Commonly this practice, it is said, acts in a beneficial manner as a tonic to the circulation. Lymphatic persons especially find it advantageous. Very neurotic or sanguine constitutions and children, again, are unduly depressed by it. The professional athlete will find here, moreover, much detailed instruction as to appliances in daily use in his calling, and likewise with regard to the systems of Schreber and the German school, the more accurately scientific Swedish system, which adapts itself to the counteraction of opposing muscular forces, the modification of the latter method devised by Pichery, and the procedure of military gymnasia. To medical men Part V., which deals with the therapeutic uses of induced or spontaneous muscular action, conveys useful information. This is especially true of the remarks on gymnastic treatment in cases of spinal curvature. Dr. Collineau advises for such cases a combination of various methods, passive and active, and lays particular and justifiable emphasis on the benefit obtained by exercises of suspension, such as rope ladders, by the manual or Swedish system, and by the regular practice of spontaneous movements calculated to strengthen the muscles on the weaker side of the body. The efficacy of similar measures is also well shown in the treatment of chorea, and paralytic nervous affections. The uric acid diathesis, the state of obesity, the sedentary habit with its attendant evils, have at all times found their truest remedy in regular and sufficient exercise. The statements which are here expressed upon this point are therefore in

Digitized by Google

accord with the previous teachings of medical science. A final chapter on the international aspect of gymnastic training is interesting in its own way; and the book as a whole may be considered to treat in a fair and comprehensive manner of the means and reasons for physical training.

OUR LIBRARY TABLE.

The Spitalfields Genius. The Story of William Allen, F.R.S., F.L.S., F.R.H.S., &c., Hon. Member of the Imperial Academy, St. Petersburg, Lecturer for many years at Guy's Hospital and the Royal Institution, and Founder of "America." Retold by J. FAYLE, B.A. Lond. and Camb., late Scholar Trin. Hall, Camb. London: Hodder and Stoughton.—The author of this pleasant little volume, who is evidently a hero-worshipper, must have devoted to it much time and patient loving labour; and his hero is particularly well chosen, for William Allen was one who unquestionably did much good work in very varied fields; who, labouring incessantly on behalf of the oppressed, the unfortunate, and the poor, himself seems to have led as blameless and perfect a life as is given to human being to live. Mr. Fayle claims that "the name of Allen ought to be for ever connected with three great schemes which have done so much to alter the whole condition of the country. 1. His 'Colonies' and general efforts to improve the condition of the agricultural labourers. 2. The 'Lanark Concern,' which led to a social revolution amongst the manufacturing hands. 3. The 'British and Foreign School Society,' which undoubtedly led to the present impulse given for general and compulsory education." The first refers to "America" or the "Colonies at Home," which Allen founded at Lindfield in Sussex, where he also tried another great experiment—an industrial school—and where he died. An amusing story is told of a startling mistake made in the case of one who, like Allen, "played many parts," but, unlike him, seems to be no sort of hero to the author. The Rev. Alexander Bell, who wrote that he thought it "an object of considerable importance to be distinguished with the honourable title of 'D.D.,'" seems to have applied for and duly received the "title of 'Doctor'—but unfortunately, through some accident, it was 'M.D.!'—and he knew as much of medicine as he did of Chinese." We have heard a story, the converse of this, of much more recent date. Some one having sent up the necessary papers and fees to a foreign bogus-degree-granting university received in return, instead of the M.D., a D.D. diploma. On writing to complain, he was informed that a mistake had been made, but that having been made a D.D., a Doctor of Divinity he must remain to the end of his existence; he could, however, by remitting fresh papers and fees, have the degree of M.D. conferred upon him as well! The book contains three illustrations and a chronological table of the life and times of William Allen, and treats of him in his various capacities as "the business and scientific man," "the philanthropist," "the courier to the Duke of Wellington," "the Quaker," and "the domestic man."

A Descriptive Catalogue of the Pathological Museum of the Middlesex Hospital. By J. KINGSTON FOWLER, M.A., M.D., assisted by J. B. SUTTON, F.R.C.S. London: J. and A. Churchill. 1884.—This catalogue is a praiseworthy production, and must prove of great value to the members of the staff, as well as to the students of Middlesex Hospital. And not to these only, for it is the custom of workers on various subjects to go the round of the pathological museums, and to such students a printed catalogue is of great service. The work is so arranged as to be easy of reference, and the descriptions of the specimens, though for the most part brief, are no doubt adequate to the purpose a descriptive catalogue is meant to subserve. We sincerely hope that the publication of this catalogue may stimulate the study of pathological specimens, for we are convinced that the majority of medical students do not give sufficient time to this section of their work. We cannot too highly praise the industry of the gentlemen who have accomplished this task.

Guy's Hospital Reports. Vol. XLII. London: J. and A. Churchill. 1884.—Sir William Gull writes on a case of probable thrombosis of superior mesenteric vein and renal veins, with detachment of several valvulæ conniventes of the jejunum followed by recovery. Dr. Hale White has a lengthy article on the theory of a heat centre from a clinical point of view. Dr. Goodhart contributes a paper on the relationship between the structural changes and the clinical symptoms of chronic renal disease associated with dropsy, and also records two cases of general anasarca in children without albuminuria. Mr. Charters Symonds describes cases illustrating the various results of partial subcutaneous laceration of arteries. A case of enlarged cirrhotic liver, with observations on the concurrence of fever with cirrhosis, is related by Dr. Carrington.

Transactions of the Ophthalmological Society of the United Kingdom. Vol. IV. London: J & A. Churchill. 1884.—It is unnecessary to praise the matter and illustrations of this fourth volume of the Ophthalmological Transactions. We may make special mention of a few of the papers therein contained. Dr. Brailey, Mr. Gunn, and Dr. James Anderson have contributed papers on Uniocular Diplopia. Dr. Gowers has written on Spasm of the Ocular Muscles. A Case of Homonymous Hemianopia has been recorded by Dr. Seymour Sharkey. Mr. J. Hutchinson's paper on Proptosis with Enlargement of Glands has more than an ophthalmological interest. Dr. Stephen Mackenzie has discussed Anæmia as a Cause of Retinal Hæmorrhage. Mr. Nettleship is the author of several valuable papers, perhaps the most wide-reaching of which are: Recovery from Amaurosis in Young Children, and Hemianopia with Cerebral Tumour. Dr. Sharkey's and Mr. Lawford's case of Acute Optic Neuritis, associated with Acute Myelitis, is of singular interest. Papers on Sympathetic Neuritis and Miner's Nystagmus are other important items.

Clinical Notes upon Two Years' Surgical Work in the Liverpool Royal Infirmary. By W. MITCHELL BANKS, F.R.C.S., Surgeon to the Liverpool Royal Infirmary, Professor of Anatomy in University College, Liverpool. Glasgow: Stephen Miller. 1884.—We have read these Clinical Notes with great pleasure. They are a very simple record of work done, accompanied by the plain practical comments of an earnest but unprejudiced surgeon. There is much sound common sense in many of the criticisms of prevailing notions. Nowhere do we feel as we read that [Mr. Banks is playing the part of the clever critic or sharp writer, but only that he is "talking" without reserve and giving us the outcome of his practical experience. We wish others who may be similarly qualified would make as good a use of the experience gained at our large provincial infirmaries and hospitals. Much good work is being done in them, and in not a few instances they afford the opportunities for gaining an experience impossible to those who live and practise in the metropolis. Those who wish to imitate Mr. Banks must, like him, avoid "making a book"—of that kind of work there is at least enough!

Mahomet and Islam. By Sir WILLIAM MUIR, K.C.S.I, LL.D., D.C.L. Religious Tract Society, 56, Paternoster-row, E.C.—This volume contains an account of the life of Mahomet from his birth until his death, and it details the various circumstances which led to his early ministry as a prophet, and to his ultimate success both in warfare and in establishing the religion of Islam. The writer does not enter into any subjects having medical aspects; thus, he merely states the facts as to the curious "trances" which

Digitized by Google

Mahomet exhibited early in life, and at a date when any attempt at imposition hardly seems indicated; neither does he seek to explain the subject of "visions," although it is evident from his account of them that some were resorted to solely for the purposes of deluding the people and of enabling the prophet to cover his own errors, or to recede from positions he had formerly taken up. There is also no account of the special sanitary regulations which the religion of Islam enforces. But those who desire to learn the story of this remarkable man, as told by an expert who has fully studied the subject by the aid of considerable experience of Eastern languages and Eastern habits, will find in the small volume much that will interest and instruct them.

A Treatise on the Purification of Coal Gas and the Advantages of Cooper's Coal-liming Process. By R. P. SPICE, Mem. Inst. C.E. London: Spon. 1884.—The author of this little book is a warm, and we venture to think a somewhat injudicious, advocate of the coal-liming process of gas manufacture invented (in its present form) by Mr. Cooper and backed by Mr. Wanklyn. Whether this process will be found permanently advantageous is more than we can say, but the gas managers with whom we have talked on the subject have certainly not been sanguine on the point.

THIRTEENTH ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD.

THE report of the Local Government Board for the year ending Lady-day, 1883, shows that, notwithstanding the increase of population, there has been a diminution in the mean number of paupers amounting to 0·7 per cent. as compared with the previous year, the reduction having been mainly due to a falling off in the number of vagrants and other out-door paupers. But whereas the rate of expenditure for 1882 had been the lowest on record, a slight rise of one farthing per head of the population has since occurred, the average charge per head now amounting to 6*s.* 4*d.* Considerable additions are in prospect in some of the metropolitan workhouses. At Greenwich new buildings have been approved of, at Hackney the erection of new blocks is in progress, the Holborn Guardians are about to provide a new workhouse at Mitcham, at St. Pancras new buildings are to be erected on some land compulsorily purchased by the guardians, the Wandsworth and Clapham guardians are erecting a new building, and somewhat similar works are in progress in Poplar and Shoreditch. So also the opening of the infirmary at Mile-end, and the approach to completion of the infirmaries at Paddington and Fulham, will nearly complete the provision for the sick poor authorised in 1867. Much improvement has in recent years been effected in this matter of dealing with the sick poor. Formerly, before the issue of THE LANCET Workhouse Commission, the medical charge at each of the several workhouses was as a rule entrusted to an unassisted general practitioner having his other work to perform, there was about one paid nurse to seventy-five patients, and there were only three paid night nurses for the workhouses of London. Now there are seventy-five workhouse medical attendants, and apart from matrons, ward-cleaners, &c., there are 610 paid nurses in the Poor-law infirmaries, 200 in imbecile asylums, and 174 in workhouses. A similar advance for the better has taken place in the structure of the buildings and in their general administration.

In view of the advent of cholera, the Board arranged with the managers of the Metropolitan Asylums Board to make hospital provision quite irrespective of Poor-law relief or of the metropolitan vestries, and the managers were informed that the Board intended, in case they put the Diseases Prevention Act, 1855, in force for the metropolis, to constitute them the "local authority" for the purpose. The vestries and district boards were, however, by no means to be exonerated from their duties, and they were told that they might be expected to make arrangements for the prevention and treatment of the disease, such arrangements to include the medical visitation of the poorer houses, the supply of medical attendance and nursing, and of medicines and disinfectants, together with the provision of places of refuge for the sick. As regards the arrangements of managers of the Asylum Board in connexion with small-pox, it is evident that the Central Board takes the responsibility as to what has recently been done, for they describe the various steps adopted and explain that their sanction was given to them in connexion with the consideration which they had given to the recommendations of the Royal Commission on Fever and Small-pox Hospitals.

Passing over many other subjects with which the report deals we come next to the subject of local government and public health. In this part of the report we learn that whereas the total loans for sanitary purposes, sanctioned under the Public Health Act, 1848, by the General Board of Health, up to Sept. 1st, 1858, was somewhat over £2,900,000, and whereas the sanctions granted by the Secretary of State under various Acts up to August 19th, 1871, were some £7,300,000 in amount, the sums granted since the formation of the Local Government Board in the latter year, amount to over £29,000,000; the loans having mainly been sanctioned for works of sewerage, water-supply, purchase of land, provision of hospitals, &c. At the present date 1116 authorities have appointed medical officers of health with a view to repayment of half their salaries out of the Parliamentary grant, and 1016 have so appointed inspectors of nuisances. In some cases the Board have altogether refused to sanction appointments of officers of healths, on account of the inadequate salaries proposed, and they have further pressed certain authorities to discontinue the practice of appointing as medical officers of health the Poor-law medical officers of the districts concerned. During the year fifty-six rural authorities have been vested with urban powers, and certain defaulting authorities have been dealt with under section 299 of the Public Heath Act, notably the Cheshunt Local Board in connexion with their persistent failure to provide means of sewerage. To several authorities has been granted the power to make bye-laws as to tenement houses.

In connexion with the Sale of Food and Drugs Act, 1875, it appears that 265 authorities have appointed analysts, and that the number of analyses made during the year has increased by 200. Of the articles thus examined 15·04 per cent. were found adulterated, spirits, milk, coffee, butter, and drugs ranking highest in point of adulteration; but it is pointed out that the adulterations are, in one sense, less serious than they were formerly. Water may, it is true, still be added to milk, and chicory to coffee, but we now no longer get such poisons as copper and sulphuric acid added to articles like pickles and spirits. Much more stringency is, however, still needed in this matter of adulteration, especially as to the amount of the fines imposed.

The system of compulsory notification of infectious disease is also adverted to in the report; and it appears that during 1883 Burnley, Hartlepool, Heywood, and Portsmouth were added to the list of places where that system is carried out. It is curious to note that whereas thirty-four towns, having a collective population of over two millions and a half, had adopted this system of notification by the close of 1883, half this population is distributed amongst sixteen towns in the single county of Lancaster. Since the end of 1883 Chester, Croydon, and Dewsbury have also adopted the same provisions. Some other matters relating essentially to the Medical Department of the Board are contained in the volume, but as these are always dealt with separately in a special blue-book, they are either subjects which we have already considered or which we shall have a better opportunity of doing at a later stage, when we deal with the Supplement containing the Report of the Medical Officer to the Board, which has just been issued.

SOUTH LONDON SCHOOL OF PHARMACY.—The following prizes were presented to the successful competitors at the School examinations held from the 3rd until the 6th of December, on Saturday the 13th Dec. 1884:—Senior Chemistry: Medal, R. Atkinson; Certificate, T. J. Clark. Junior Chemistry: Medal, F. W. Taylor; Certificate, F. B. Bennett. Senior Botany: Medal, T. J. Clark. Junior Botany: G. D. Cooper. Materia Medica: F. B. Bennett; Certificate, F. W. Taylor. Pharmacy and Practical Dispensing: F. W. Taylor; Certificate, F. E. Brown. Extra Certificates of Merit: Messrs. Gooch, Marshall, Brown, Davies and Daintree.

THE LANCET.

LONDON: SATURDAY, DECEMBER 20, 1884.

THE great dissatisfaction with the arrangements for university education in London which has been so freely expressed in teaching circles and in the press has now taken a definite shape. On November 3rd a circular letter was sent by Lord REAY to those who were known to be anxious for the establishment of a Teaching University, on the 10th a subcommittee was appointed to draw up a report for presentation to the general committee, and the members were so expeditious that a scheme was laid before the teachers of London and others at the Society of Arts on Monday last. Lord REAY presided over a very crowded and representative meeting, at which Sir GEORGE YOUNG and the chairman were the principal speakers. Although there was some divergence of opinion as to the best means of securing a true university education in London, there was a complete unanimity as to the misfortune of having a mere examining board in the position which in every other city is occupied by a true university. The objects aimed at by the committee had the sympathy of every speaker, and the report was received and taken as a basis for more matured action. Association of university examination with university teaching, and the conferring of a substantive voice in the government of the university upon those engaged in the work of university teaching and examination, are the essentials of the whole scheme. Affiliation with existing institutions in London and alliances between the new university and the professional corporations, although of great importance, must be secondary considerations. If the University of London, which now occupies the ground that a real university should have filled, be too tenderly considered, the scheme must of necessity become abortive; and this, we fear, is the rock ahead in its course. A fortnight ago we showed, from the composition and mode of election of the Senate, how little hope existed that the present University could ever be expected to move from its present course and come into cordial relations with the professoriate. Twenty-four Crown nominees and twelve Fellows chosen by Convocation from the different Faculties alternately, and all elected for life, and with scarcely an active teacher, at the present time in the whole body, can have but little real sympathy with the present movement, and are unlikely to be expected to vacate their seats for younger professors so that the real teachers may form a majority in the Senate. Nor is it to be anticipated that they will admit that their policy in the past has been a mistaken one, and apply for a new charter omitting the 36th clause in the charter of 1863: "Persons not educated in any of the said institutions shall be admitted as candidates for any of the degrees [illegible] to be conferred by the said University other than degrees in medicine and surgery." Unless this be done how can the two bodies be represented on the same council, or how can they work harmoniously side by side, when each is a standing protest against the ideas and procedure of the other? The University of London should give up its restrictions and regulations for degrees in medicine and surgery as it has done in all its other faculties. "Free trade in education," and an "examination test," are its characteristics, and they should be fearlessly and logically carried out. It would then become a great examining board for the British Empire, and perform a great work for which it is well fitted, and which it has successfully carried out in the non-medical faculties. There would then be room in London for a teaching university, which would confer degrees only on the students who had passed a definite curriculum under its own professors and teachers, and who would, with outside assessors, examine their own pupils, as is done in all other universities. Teaching and examining would go hand in hand. By such means different functions and a different work would be given to each university, and all clashing and jealousy might be averted. The endeavour to weld together discordant institutions and divergent systems must always end in failure. University and King's Colleges, the Schools of Medicine and Law at present in existence, form a nucleus which could be utilised as the bases of the new university, and which might perhaps enlarge and develop at a future time, and form alliances with the professional and other corporations. A modest scheme is always the best one with which to begin. The Victoria University in Manchester is the pattern on which the proposed university should be constructed, but this cannot be followed if any compromise *with closed doors* be arranged between the committee and the Senate of the University in Burlington Gardens.

THE Metropolitan Sewage Discharge Commission, appointed in 1882, has issued its second and final report. It will be remembered that in their first report the Commissioners proved the existence of the nuisance complained of by evidence that placed it above doubt, but reserved the far more difficult question of a remedy for further consideration. The new report is in several respects very satisfactory. The hot summer of 1884 has rendered the condition of the river so horrible that some very strong supplementary remarks on the evils of the present system have been added by the Commissioners. On one occasion, three out of five Commissioners, and also their clerk, suffered from severe diarrhœa after their day's inspection. The sewage was perceptible by sight as well as smell throughout a large area. At Greenwich pier "the water was very black, and the smell excessively strong." At Woolwich, "the river for its whole width was black, putrid sewage, looking as if unmixed and unalloyed. The stench was intolerable." At Erith the smell was strong, and in Erith Reach the sewage was clearly visible and the water dark," and so on at all the points visited down to Greenhithe. It is not wonderful that the unfortunate visitors should have summed up their experience in such trenchant words as the following: "We found a condition of things which we must characterise as a disgrace to the metropolis and to civilisation." The state of the river in the past summer was actually too much for the Metropolitan Board, who have gone so far as to have admitted the existence of the nuisance in the present year," an admission, however, hardly in accordance with their previous broad statement that they [illegible] conclusions arrived at by the Commissioners [illegible] their first report."

Digitized by Google

Having thus confirmed and emphasised their previous conclusions, the Commissioners set to work to find the best remedy. Here, unfortunately, they have been far less successful. They received but little assistance from the authorities who had fought so keen a battle before them in the earlier stages of the investigation. The interest of the Corporation of London seems to have cooled as quickly as it became heated, for the Port Sanitary Committee refused to move further in the matter, thereby showing how ill calculated such a government is for the consistent defence of public interests. The Metropolitan Board of Works also refused to tender evidence, although they allowed their engineer, Sir JOSEPH BAZALGETTE, to assist the Commissioners with his advice. Thus left to their own resources, the Commissioners seem to have done all that was possible for them to do. They took the evidence of all the experts they could gather, collected and studied all the literature of the subject, and visited many towns where processes of sewage treatment were in use. It is rumoured that not infrequent differences of opinion occurred among them, as well they might, and at last they had to content themselves with recommendations which, though valuable enough as far as they go, are by no means so definite as we had hoped to obtain. The difficulties of the question are indeed enormous, and are well illustrated in the able historical sketch which occupies twenty-seven pages of the present report. For the last thirty years and more scheme after scheme has been tried for the disposal of town sewage, and some have met with partial success. But it cannot be said that any one of them has proved quite satisfactory. All, under the conditions prevalent in the Lower Thames, would be expensive; and as there is now no doubt that some scheme must immediately be adopted, it only remains to choose the one which with real efficiency promises to be least costly. Sir JOSEPH BAZALGETTE proposes the extension of the present sewer, united into one by a conduit under the river at Crossness, to Thames Haven, thirty-six miles below London-bridge by river, but, with characteristic persistency, he urges that the sewage should still go into the stream in a raw state. We are glad to find that he is quite alone in this last opinion. It is, moreover, anomalous that the engineer who has so long and so stoutly opposed this extension should now himself propose it.

On the whole there seems to be a consensus of opinion, heartily adopted by the Commissioners, that the sewage must be taken to Sea Reach. What to do with it there is less certain. Carry it still further and throw it into the sea, say some engineers; and it is very possible that this might be the cheapest course, but there are many objections to it; and were entirely in accord with the Commissioners in believing that the proper system to adopt is that which is generally known as precipitation supplemented by application to land. Let the sewage of the whole metropolis, including that of the Lower Thames Valley, be taken in a single conduit to Canvey Island, below Thames Haven; provide sufficient land for intermittent downward filtration; precipitate the solid matters by the cheapest available process; apply the solid matters as manure to the land, thereby fertilising it and raising its level; irrigate the land with the fluid portion, and throw only a decently clean effluent into the river. All this would doubtless be expensive, but it is necessary, and we believe that if a Parliamentary committee were appointed to fix the means it would be found to involve no greater expense than the metropolis could bear.

Meanwhile some temporary precipitation process should and must immediately be adopted at the two great outfalls. We cannot too often repeat that the fearful danger of cholera hangs over the land, and if no preparation is made for it before next summer a most serious responsibility will lie with our rulers. Let us conclude in the words of the report before us, embodying as it does the opinions of Drs. STEVENSON and DE CHAUMONT, the medical members of the Commission:—"The condition of the river is such as to be a danger to health; and in view of the probable arrival on it of vessels with cases of cholera on board, should the state of the river not improve very speedily, the gravest results may be apprehended."

THE adjourned discussion at the Clinical Society, whilst fertile in the presentation of various views, brings us no nearer the truth as regards the nature of CHARCOT'S disease. The remarks of Mr. BARWELL, who began the discussion, referred chiefly to the differences which mark the contrast between typical forms of the disease. When such a method of treatment of the subject is adopted we cannot expect much more than a mere statement of facts. The explanation of the disease by such a method is hardly an exposition of the nature of processes, but is rather a descriptive commentary on the matter in hand. Of etiology Mr. BARWELL said but little; he seemed to think that the nervous system played an important part in the production of both chronic rheumatic arthritis and tabetic arthropathy, though the kind of nervous influence was not regarded as of identical nature in both affections. Sir JAMES PAGET, who followed him, treated the matter in a more philosophical and argumentative fashion. In the present state of our knowledge, it is not possible to make dogmatic assertions on the nature of the disease in question, and Sir JAMES took care merely to lay down the lines on which we might expect to explain the pathological relationships of chronic rheumatic arthritis and the joint affection of locomotor ataxy. He regarded the malady as of the nature of a new disease—not actually a brand-new affection, but a disease compounded of various constituents, whilst the resultant of such components bore little resemblance to the parent roots from which it sprang. To explain more fully the kind of view he would take, he presented for consideration other instances of disease, with the object of showing how a mingling of causes might produce a variety of effects having but little resemblance to the antecedents which played their parts in the production of such compound results. Next, as new species of animal and vegetable life have become evolved by the interaction and intervention of a mixture of pre-existing influences, so have new species of disease been produced under the guidance of like laws of evolution. New combinations arise, and alterations are effected in the aspect of disease, just as happens in other spheres of nature. The marriage of rheumatism with syphilis, or gout, or tubercle gives rise to new compounds of disease in which it is difficult to separate the individual influence of each of the factors. The task of the pathologist should be to endeavour to unravel the threads which composed the skein; in other words, to decompose the patholo-

Digitized by Google

gical compound, and seek to ascertain the number and arrangement of units of rheumatism, or syphilis, or the amount of nervous influence, or what not, which may have entered into the composition of the complex disease. Sir JAMES considered that CHARCOT'S disease might be a species of chronic rheumatic arthritis, modified by its occurrence in a patient the subject of locomotor ataxia, or altered from its pattern by the intervention of the nervous disease. He believed that an error of nerve force did determine a lesion of nutrition, whether in the skin or elsewhere, but he also believed that such error of nervous action was not the sole element in the etiology; that in the causation of herpes zoster, for example, a nervous disturbance was acting there could be no doubt, but the nature of the cutaneous eruption was influenced by other agencies. Why should an error of nerve force give rise to a vesicular eruption, instead of to a scaly or ulcerative one? The disorder of nervous influence might excite a morbid action, but other factors, such as rheumatism, gout, syphilis, or this or that diathesis, gave character and colour to the morbid process. It might be argued against this view that errors in nerve force need not all be of one kind, and that nervous disturbances may vary in quality and quantity.

Dr. MILLER ORD was the only physician who joined in the debate on its first adjournment. He was inclined to think that the distinctions between the joint affection of tabes dorsalis and chronic osteo-arthritis would not bear close investigation. Even in cases which were roughly grouped under the head of chronic osteo-arthritis great differences prevailed. The evidences of a neurotic influence of a direct or reflex nature in the case of many diseases of the joints were no doubt strong, yet it must be confessed that many other causes might give rise to similar changes in the joints. Professor HUMPHRY introduced a new consideration by instancing the case of intracapsular fracture of the neck of the femur of old people. He was struck with the exuberant growth of bone in the neighbourhood of senile fractures as contrasted with the general atrophy of the osseous system, and he drew a parallel between CHARCOT'S disease and the repair of fractures in old people. He did not concur in the opinion that the disorder of nervous influence in locomotor ataxia allowed of no reparative process in the bones, and he referred to specimens in illustration of his opinion. Mr. JONATHAN HUTCHINSON believed that in lesions of nutrition in which the nervous system took part the disease was due, not to the active interference of the nervous forces, but rather to their passive permission of disease. Perforating ulcer of the foot was a local lesion, possibly started by an injury and permitted to continue by the unobservant or anæsthetic attitude of the afferent nerves, whereby continued pressure on the part was allowed to go on, since the patient was not in a position to feel pain owing to the diseased state of the nerves going from the foot. He thought the fact that such ulcers tended to get better when all external causes of disturbance were removed supported his views. In locomotor ataxia he saw a malady which might be looked upon as "a sort of tumultuous old age, a premature senility of the nervous system." Mr. WHITAKER HULKE sided with the opinion that CHARCOT'S disease was chronic rheumatic arthritis modified by circumstances. After having shown how the contrast between typical cases of the two affections would not hold good when less well-marked specimens were studied, he proceeded to point out that even in the clinical course joint affections occurring in locomotor ataxia might assume all the characters of an acute synovitis.

At the second adjournment, the principal speech of the evening was that which occupied Dr. MOXON fifty minutes in delivering. It is needless to say that the speech was characterised by wittiness of word and thought, and exhibited considerable powers of originality of conception. We are unable to agree with the views implied by Dr. MOXON on the trophic nerves, which have, in our opinion at all events, a functional if not a structural existence. Dr. MOXON lost sight of the usually rapid onset of CHARCOT'S disease when he endeavoured to show that the joint of the cabman might have been a typical case of the disease if some of the nerve symptoms of locomotor ataxy had been present. The speaker also apparently forgot that though the dilatation of the arterioles in muscular action is a fact, yet the nerves by which such a dilatation is brought about are probably not the same as those by which the muscle is made to contract; it would therefore be necessary to prove that the *vessels* in and about the paralysed glutei were in such a state as to prevent proper nutrition of the tissues. Mr. MORRIS was inclined to accept the views of those who agree with Mr. HULKE, and in more or less agreement with these doctrines Dr. PYE-SMITH'S speech may be placed. Mr. HERBERT PAGE was an unhesitating supporter of CHARCOT'S disease as a distinct malady.

THE relations between physician and patient are in many instances necessarily of so confidential and intimate a nature, that it is not surprising if from time to time cases occur which disturb the public mind. It is doubtful whether the trusted solicitor or the trusted medical practitioner is taken the more unreservedly into confidence, but each in his way is necessarily admitted freely behind the scenes. It may at once be granted that a medical man enjoys opportunities, and is indeed forced to occupy positions, which were he not a medical man would have no explanation but a criminal one. Under these circumstances it becomes advisable to lay down some of the principles governing these relations; and in this connexion we may say at once that while the medical man who is base enough to misuse his opportunities is a villain, whose punishment is desirable not more for the sake of the public than on behalf of the noble profession which he has degraded, the medical man unjustly attacked is a person for whose protection every generous mind, whether lay or medical, will claim the severe punishment of his traducer. To lay a hand on a person without cause is an assault in the eye of the law; it is conceivable that to feel a person's pulse against his will might form the ground of an action, though to look at a tongue or to touch it could not, since the patient must first willingly protrude it, thus consenting to the action. If the mere feeling of a pulse may constitute an assault, to examine the chest of a female patient against her will might be interpreted as an indecent assault; but the question naturally reaches its climax in cases where a pelvic examination is indicated. Here it becomes necessary for the medical man to be cautious, for the consent of the patient is essential. Such examinations being sometimes painful,

Digitized by Google

patient may be most anxious to submit, and yet present insuperable obstacles to such an examination. On the other hand, a patient may submit, and afterwards protest that she objected; such cases are not unknown. What certainty can the medical man possess? how can his footing be firm? It may be at once stated that a patient who comes to a doctor's house complaining of pelvic mischief presumably contemplates that it may be necessary to undergo a pelvic examination, while if she places herself in a suitable position at the doctor's request, the act of so placing herself definitely gives her consent. The doctor, however, will do well, in case of any hesitation on her part, to explain to her that he cannot treat her without knowing what is the matter, and that this can only be ascertained by the usual examination; moreover, that *he* will not consent to make such an examination unless requested by her. We are far from saying that a pelvic examination is necessary whenever pelvic symptoms are complained of; in the case of virgins nothing but urgency will induce the high-minded medical man to make such an examination, and in the case of any woman the indications for such an examination must be clear to make it justifiable. In any case, however, the doctor must be the judge of such necessity, and it is to be presumed that if an examination has been made, it was necessary.

A medical man is exposed to another risk in dealing with pelvic diseases—namely, to that of being accused of unnecessarily protracted visits. It may be safely asserted that to do justice to these cases takes a longer time than is required by cases in any, or almost any, other department. In hospital practice, even if the cases are previously selected, so that all but local conditions are mostly eliminated, each new case may take twenty to twenty-five minutes; while in private, where nothing is previously known of the patient, and the whole organism may require consideration before sufficient grounds are found to justify a pelvic examination, thirty to forty-five minutes may be consumed. In subsequent visits the time required is generally shorter.

The question has before now been raised, whether in all these cases a third person should not be present. To this we will say that, from the patient's side, she should never enter the house of a man who, in her opinion, requires such supervision. But to have a third person present is, as a matter of fact, usually declined by the patient, even if the person be her own relative who has accompanied her. Generally speaking, the presence of a third person is a matter of indifference, or even of satisfaction, to the doctor; but the patient may be compelled to relate matters which render the absence of a third person more in accordance with delicacy. But there are undoubtedly certain precautions which common sense and good feeling suggest. The first is the practice of taking notes of each case at the time. Hysterical and intemperate women are undoubtedly dangerous; note of these states should be made, and the medical man should avoid pelvic examinations as far as possible, and in this special case may reasonably ask for the presence of a friend. Anæsthetics should never be given by a solitary doctor to his patient; the state of intoxication produced not unfrequently takes an erotic turn. It is usually advisable to avoid mixing social with professional visits; a doctor visiting as a doctor should play the doctor, and not the visitor; he may visit as a visitor at another time. In cases of domestic unhappiness or separation he should be doubly cautious. Finally, in case of any apprehension of foul play, the medical man should take into his confidence some one, at least, of his professional brothers, and, on the first indication of a charge being made against him, should attack his accuser with all his force. More than one pure reputation and innocent life has been lost just for the want of a little courage. The assumption of the aggressive is not only the proper course in such a case, but it goes far to carry conviction to others of the innocence of the aggressor, on the principle that "the righteous is bold as a lion."

THE questions at the first examination which has taken place under the new regulations for the promotion of surgeons-major, and which will be found in another column, appear to us fully to justify the course followed by the military authorities in establishing such a test. It must not be forgotten that the principle laid down in accordance with the recommendation of the Royal Commission presided over by SIDNEY HERBERT was, that promotion to the administrative ranks should be not by seniority but by selection; that while promotion to the rank of surgeon-major was ensured to every officer entering the service, unless he was proved to be incompetent, the higher grades were to be filled up by selection of the men best fitted for the administrative duties required of them. But no special rules were laid down as to the manner in which this selection was to be made or the knowledge to be acquired of the qualifications possessed by the officers eligible for promotion. For some time after the Warrant of 1859 came into operation they were selected by the Director-General; but under the rule of Sir T. G. LOGAN the system degenerated into that of seniority, unless there was evidence of the incapacity of the officer. Under the present organisation of the medical department, with its increased powers and consequently increased responsibility, it would be impossible to carry on the service satisfactorily on such a system. The Director-General is entitled to ask some guarantee that the officers to be selected for promotion are acquainted with the nature of the duties which will devolve upon them in their new position, and the rules and regulations under which these are to be conducted. In what manner can he obtain the information necessary to enable him to judge on this point? It has been said that he has the means in the confidential reports of the general officers and of the administrative officers of his own department. But it must be evident to anyone acquainted with the service that a general officer has neither the knowledge nor the opportunity to enable him to form an opinion on this point, and although the Principal Medical Officer may be able to satisfy himself on the subject of a surgeon-major's efficiency as an executive medical officer, he has no means of ascertaining the amount of knowledge he possesses on the subject of administrative duties. The examination as now authorised appears to be the only method by which the Director-General can obtain the information necessary to enable him to form a correct estimate of the qualifications of the officers to be selected for promotion. It has also the advantage of affording an opportunity to an officer, who from the exigencies of the service may never previously have had one, of showing that he possesses

Digitized by Google

those very qualities which peculiarly fit a man for administrative work, and which are of so much importance in promoting and maintaining the efficiency of a department. We cannot sympathise with those who object to such an examination as derogatory to a medical officer. We rather look upon it as an opportunity of proving his special fitness for advancement. If the Director-General is permitted to carry out the system honestly and fully, we have no doubt it will tend greatly to the efficiency of the medical service, and to the advantage alike of the soldier, the medical officer, and the profession.

Annotations.

"Ne quid nimis."

THE REMOVAL OF SMALL-POX PATIENTS.

MR. COLLIER, medical officer of health for the Fulham district, has addressed a report to his authority on the subject of the removal of cases of small-pox from that district to the Fulham Hospital; and it concludes with advice which, if followed, would involve action of a distinctly retrograde character. He maintains that his authority can more effectually remove such cases than the Asylums Board, and he adduces a number of reasons to prove this. Thus, he implies that the unwillingness of patients to submit to removal can be got over by the sanitary officials better than by the Asylums Board officials. This is quite true; but we fail to see why the sanitary officers, who have called in the Asylums Board ambulance and whose presence in the infected house is necessary to disinfection immediately on the removal of the patient, should fail to use their powers of persuasion when one ambulance is employed instead of another. Then, again, he refers to the legal powers to enforce removal which are possessed by the sanitary authority, but which the Asylums Board do not possess. Here, too, we fail to see what this has to do with the ownership of the ambulance. Throughout the country and in the metropolis sanitary authorities exercise their legal powers in this respect under the circumstances which Mr. Collier does not regard as applicable to Fulham, without any question arising as to the ownership of the ambulance. The fact is that the removal of the patients by a number of different bodies was carried out in so scandalous a manner that public opinion demanded a change, and the Asylums Board, in deference to this opinion, has established ambulance stations in various parts of the metropolis, including Fulham. That they can do the work efficiently is most certain; and it is far better that a single body should be responsible to the public in this matter than that it should be vested in a number of authorities, many of whom have hitherto only brought the question into disrepute. An efficient ambulance station and staff exist in Mr. Collier's district, and will be maintained there whatever the Fulham Board decide; and it seems to us that the local people had better make use of it instead of maintaining an opposition one at their own cost. On one point, Mr. Collier may perhaps have a reasonable grievance. He says that the Asylums Board do not always give notice of the removal to the sanitary authority. The fact that he singles out an individual case in order to prove this seems to imply that the case was quite an exceptional one, and in view of the general practice adopted by the Asylums Board we have but very little doubt that the omission was a mere accident. Under any circumstances any such default can easily be remedied, and it bears no comparison with the gross irregularities which local authorities were in the habit of perpetrating previous to the establishment of the Asylums Board ambulance stations—as, for example, the habit of permitting relatives of the sick to [illegible] patients, and then to diffuse the poison right [illegible] the hands of the Asylums Board such grave [illegible] is certain not to recur, and we hope they will [illegible] in taking over the whole work of the re[illegible] of fectious sick to their hospitals.

FOOD AND STUDY IN ELEMENTARY SC[illegible]

IN former articles we have reviewed the evi[illegible] educational over-pressure in elementary schools, [illegible] reference to its causes remote and near, and to [illegible] upon the children in their bodies, minds, and mor[illegible] modes of application of this pressure are various[illegible] results must not be gauged by the proof of lunacy [illegible] alone, but by considerations of the general healt[illegible] children exposed to it. Its removal consequently [illegible] wide and intelligent inspection and adjustment of t[illegible] working of infant school machinery, the state of the[illegible] and the influence of one of these factors on the [illegible] has always been clear to our minds that a chief p[illegible] kept in view in dealing with this question has [illegible] preparedness or not of a child in regard to nutriti[illegible] work imposed upon it. There is too great a te[illegible] take fitness in this respect for granted, yet we hav[illegible] think of the shiftless parentage of so many who co[illegible] School Board influence, of the hunger and inevi[illegible] which prevail, among even the deserving poor out[illegible] to know that here we touch the core of the subject. [illegible] the laborious boon of education on brains which are [illegible] and while rest is perhaps the only kind of bodily t[illegible] which can be borne, is to block with good intentio[illegible] the avenues of intelligence and of health. It is n[illegible] sary to do more than to recall in the briefest t[illegible] reasons for the all-important power of food in ch[illegible] Not only does it represent a certain latent energy [illegible] work to be done, but at this age more than any oth[illegible] go to that continual work of building young [illegible] mental tissue, apart from its sustenance while [illegible] which we recognise as growth. Eminent [illegible] tissues in its rapid development in size and powe[illegible] brain; nor is it unrivalled while bone and muscle, t[illegible] structures most subject to strain and pressure, exhi[illegible] usual strong vitality. The lymphatics again, th[illegible] most corruptible by hereditary taint and that whi[illegible] ters to every organ its supplies, must be liberally f[illegible] maintenance of body heat is likewise admitted [illegible] special need of childhood, and a preventative of its m[illegible] liar ailments. This no artifice can accomplish if [illegible] changes be restrained by want of food. Under [illegible] these facts we would not be too careful in meas[illegible] advocacy of the plans by which it is sought to [illegible] ficient nourishment for the needy learners in el[illegible] schools. We have more than once had occasion to [illegible] the institution of penny dinners, which owes its [illegible] the thoughtful enterprise of Sir H. Peek, an[illegible] experience has already shown to be a good out[illegible] portion to its cost. Cheap though the provision [illegible] ever, it does not meet the case of many whose [illegible] cannot be relied upon for even a daily penny wo[illegible] charity would be illusory indeed which would [illegible] sanction and help a penny fund established for [illegible] of proved *bonâ fide* cases of this kind. In a[illegible] where spontaneous giving has long since [illegible] regularity of law when once its object is realised, [illegible] not be hard to find the food without recourse to a [illegible] or imperial grant. Why should not the churches [illegible] poor district combine to organise and guide [illegible] system of relief as we have suggested? It [illegible]

Digitized by Google

mess, with weekly payment in advance, aided in carefully selected cases by a charity fund, would conduce to regularity of attendance, as it certainly would also promote a wholesome mental culture.

THE PARKES MUSEUM AND CHOLERA PREVENTION.

A MOST successful series of lectures organised by the Parkes Museum on Precautions against Cholera has just terminated. The first lecture dealt with precautionary measures from a national point of view, and Mr. Ernest Hart, the lecturer, evidently had the complete assent of a skilled audience in his contention that the whole course of the epidemic in Southern Europe had gone to prove once more that quarantine, both by land and sea, was a useless, mischievous, and, if stringently carried out, a cruel expedient when applied to European and other populous countries. On the other hand, medical inspection and isolation at the ports were advocated; and, in view of the etiological similarity of cholera and enteric fever, it was maintained that the country should never cease in its endeavour to remove from amongst the people those conditions which favour the propagation of the latter disease if they would secure themselves against the spread of the former. Mr. Shirley Murphy discussed the next subject, and, having regard to the position which he holds amongst medical officers of health, the advice which he gave as to the duties of sanitary authorities and of householders, in face of the possibility of the importation of the disease, should carry considerable weight. Means for the earliest possible detection of any choleraic cases, and provision near at hand for the immediate isolation of the patients, should be everywhere available; and both sanitary authorities and householders should secure the utmost cleanliness as regards air, water, and food. Dr. Norman Chevers, in the third lecture, brought his extensive Indian experience to bear upon the subject of the precautions to be taken by individuals. He urged that no person should be content to live in a house which was pervaded by sewer and other unwholesome emanations; that during an epidemic period excessive fatigue and exhaustion, as also exposure to sudden variations of temperature, should be avoided; that flannel in the form of a cholera belt had an unquestionable value; that the greatest care should be taken as to drinks—ginger beer, bottled lemonade, and cask ale being eschewed; and that everyone should be prepared to check the earliest onset of diarrhœa. Where such precautions were taken, manly resolution needed to be combined with the necessary prudence and moderation, and thus panic, the most dangerous and degrading of all the conditions with which cholera prevalences have been associated, would be avoided, and many lives would be spared. The Parkes Museum would materially aid in furthering the work they have set themselves to do if they were to issue the set of lectures as a whole. Their influence upon legislators, sanitary authorities, and individuals could only be for good.

THE NEW HOSPITAL FOR NORTH LONDON.

IT is announced that at length a site has been bought for this institution—namely, Grove House, in the Holloway-road. Much delay has arisen since the important meeting in Highbury; but the Committee has not been altogether to blame. The situation might have been a little more central, yet it will lie in the centre of a very large population. It is intended in the first instance to have 120 beds. But if the generosity of the public rises to the height of the need this number should soon be doubled. It must be remembered that the new hospital is to include and absorb the Great Northern Hospital.

MURDER FOR FOOD.

IT is to be regretted that the farcical proceeding of pronouncing a sentence which is not to be carried out should have been deemed necessary to vindicate the claims of justice in the case of the survivors from the *Mignonette*, who in the agony of their starvation in an open boat at sea committed murder. There can be no question in common sense, and it is satisfactory to find that there is no question at law, that these men are guilty of murder. It matters nothing to the nature or importance of the deed that it was a murder not for theft or malice but for food. The dictum of Lord Hale is, happily for the honour of human nature and the dignity of English law, affirmed: a man "ought rather to die himself than to kill an innocent." There must be an actual attempt on the part of the person killed to murder the man who kills him, or the act of putting him to death will be murder. A threat to kill is not sufficient without the overt act of trying to kill. It is not the necessity of the man-slayer, but the guilt of his victim, that makes the act of homicide justifiable. It could not of course be contended that the poor boy Parker, the youngest, and therefore the most to be pitied and protected, of the survivors of the *Mignonette*, had any guilt to justify the assault of his not less unscrupulous than hungry murderers. For the credit of human nature, and more especially of the class of men "who go down to the sea in ships," we will not believe that it would be easy to find other men who, being placed in such a dire strait as these, would have fallen upon the youngest of their number, the one who of all others had the greatest claim on their forbearance, and deliberately murder him for food. The tragedy enacted in this open boat, look at it as we will, is so terrible and revolting that the brain reels and the heart faints with conflicting compassion and indignation as we think of it. With infinite relief the blood-stained and humiliating page may now be turned down for ever. With too tardy forms Justice has confirmed the judgment of reason and humanity. The miserable men who committed this great crime against their nature and the laws of every civilised State, preferring to kill the innocent boy specially confided to the care of the man who ultimately murdered him, have been convicted of this deed of blood and justly sentenced to be hanged. That sentence is not, of course, to be carried into effect, but it is, as it must and ought to be, to the clemency of their Sovereign the offenders owe their lives. The imprisonment for a short term, which has been substituted for the death penalty, is necessary to mark the view which Justice takes of the wrong done. Had these men been mentally incapacitated for the formation of a judgment of right and wrong by the deprivation of food, that might have been pleaded in their defence; but no such plea was permissible in face of the fact that they not only clearly recognised the nature of the wrong they did, but they set about it in the most methodical manner, and were so cool in their reasoning that they actually murdered a boy they believed, or profess to have believed, to be dying, instead of waiting for his death, in order that the blood in his body might not coagulate before they could drink it. Hideous foresight—false in facts, but horribly sane in its reasoning. As a matter of fact the blood of a creature dying of starvation would not have coagulated, but these men could not be expected to know that. However, the use they made of the smattering of knowledge they possessed entirely precluded the adoption of insanity as a defence. Let us hope no such extremity may ever again befall British seamen; but if it should, it is well that this miserable case has so ended as to demonstrate that in law, as in the conscience of humanity, a man should far rather die than kill the innocent, even though it be murder for food.

REFORMS AT THE COLLEGE OF SURGEONS OF ENGLAND.

THIS afternoon (Friday) an extraordinary meeting of the Council of the Royal College of Surgeons will be held to receive the report of the Committee to whom were referred the recommendations and suggestions of the Association of Fellows. On Jan. 2nd the President and Vice-Presidents will receive a deputation from the Association of Members respecting certain changes to be suggested in the new Charter in the interests of Members of the College. The tenour of these suggestions may be gathered from the letter which appears in another column signed by the Honorary Secretary of the Association of Members.

THE GERMICIDE POWER OF DISINFECTANTS.

THE Proceedings of the Royal Society of Edinburgh, just published, contain the results of an important research by Mr. A. Wynter Blyth. In experimenting on the chief disinfectants of commerce, with a view of ascertaining their power of destroying the spores of the anthrax bacillus, the author's object was to determine whether any of the disinfectants in popular use had a "germicidal" action or not. Very few have distinguished between the action of a *germicide* and that of a *disinfectant*. Angus Smith, Crace Calvert, Bucholz, and other workers, have studied the inhibition of fungoid growth and of putrefaction, the destruction of odours, and the decomposition and fixing of noxious gases. But the action of chemical agencies on those minute particulate substances which are regarded as the *materies morbi*, or seeds of zymotic and parasitic diseases, have been but little investigated, with a few notable exceptions—Gerlach and Franck's experiments on the virus of glanders, Ledra on that of ovine variola, and Braidwood and Vacher on the lymph of vaccine. Closely following the method pursued by Dr. Koch in his monograph, "Ueber Desinfection," Mr. Wynter Blyth chose the anthrax bacillus as the organism best adapted to try the germicide power of disinfectants. It certainly possesses the advantage that its morphology and life history are well known; and, when its vitality is otherwise doubtful, it admits of being put to the almost unerring test of inoculation. Experimenting with a supply of anthrax bacilli in the spore state, placed at his disposal by Dr. Klein, and adopting the strictest precautions in sterilisation and cultivation, Mr. Blyth obtained a number of results, of which the principal may be thus briefly summarised. A 1 per cent. solution of Calvert's carbolic acid No. 1 in water, seemed to have no influence on anthrax spores, not even delaying their growth. Even after soaking for twenty-four hours in a 10 per cent. solution of carbolic acid, the anthrax spores inoculated into a guinea-pig killed it in two days, with typical anthrax poisoning. Spores soaked for twenty-four hours in undiluted carbolic acid did not afterwards develop, but they did so after six hours' soaking in a 25 per cent. solution in alcohol. Various carbolic powders were made into a paste with water; but though the anthrax spores were allowed to rest in the paste, even as long as twenty-four hours, no germicidal effect was noticeable. Undiluted liquor carbonis detergens, which is a solution of certain coal-tar products in spirit, arrested the growth of anthrax; and it was also distinctly retarded by soaking for four hours in a 10 per cent. watery solution of the same agent. Sanitas fluid, emulsion, and oil, only retarded the spore growth; but sanitas powder had no influence whatever on it. The sulphates of iron, copper, and zinc, which are reputed disinfectants, in no case exercised any destructive influence on the life of anthrax spores. Of chloride of zinc, Dr. Koch has given a very unfavourable opinion as a disinfectant; and as a germicide, Mr. Blyth [illegible] no more favourable of it. He found that anthrax spores [illegible] solution of chloride of zinc; and the addition of thymol in no way altered the result. Perchloride of iron was experimented with in watery solutions of various strengths, from 1 to 25 per cent.; but in no single case did a twenty-four hours' steeping of the spores destroy their vitality. With the stronger solution the vegetation was late; but ultimately luxuriant. With a 1 per cent. solution, the development was more rapid than usual, the growth being, as it were, stimulated. Guinea-pigs died with all the symptoms of typical anthrax when inoculated with spores treated with [illegible] or mercuric chloride. The virulence of anthrax has long been notorious, and Mr. Wynter Blyth's research confirms it, proving indeed that it resists successfully most chemical agencies. Granting that the germs of few diseases may have such intense vitality, the research under notice suggests serious doubts, as to the germicidal power of the [illegible] and disinfectants in ordinary use.

SUPPOSED MURDER AND MUTILATION.

ON December 8th Dr. Danford Thomas, Coroner for Central Middlesex, concluded an inquiry into the identification of some human remains recently discovered in various parts of the west-central district. From the medical evidence it would seem that the parts belonged to a body of a female, and the condition of the teeth pointed to the conclusion that the probable age of the deceased was between twenty-five and forty. The viscera were wanting, but there were portions of the skeleton. Mr. Lloyd, [illegible] surgeon of police, was of opinion that "there were signs of skill in the disarticulation of the joints, the removal of the internal organs, and the separation of the limbs from the body." This raised the presumption that the [illegible] might have been used for anatomical study, and [illegible] scattered by some one who had gained possession of [illegible] either out of sheer wantonness or for the purpose of [illegible] a scare. Mr. Winter Blyth, analyst for [illegible], deposed to finding chloride of lime adhering to the [illegible], a fact which to us seems to negative the supposition that the body had been used for dissection or operation. The coroner exercised a wise discretion in pointing [illegible] the jury that in all likelihood a murder had been committed. At the same time we fail to see the evidence to warrant that portion of the verdict which runs as follows:—"That positive an abortion had been, previous to death, either attempted or completed." To say the least, it is not on all fours with Lloyd's suggestion, that the internal organs had been removed either to attempt to hide the sex or to disguise the real cause of death. All that can be said with any approach to certainty relates to the age and sex of the deceased; little stress can be laid on the appearance of dismemberment in the face of the circumstance that the body had been preserved by bleaching powder. It is [illegible] known that this substance retards the decomposition of animal matter, and so tends to thwart the designs of the murderer, as witness the evidence afforded by the exhumation of the body of Harriet Lane, the victim of [illegible]. Quicklime, on the contrary, has a corrosive action when applied in quantity soon destroys the soft tissues. Advantage is taken of this property in the disposal of the corpses of those who have succumbed to judicial [illegible]. It was a curious coincidence that not long before the finding of the subject of the inquiry under consideration [illegible] limb and two feet were found in Moreland Street, in the latter case the parts had evidently been [illegible] so the coroner ordered them to be buried. By the Home Secretary, however, they were [illegible] comparison of the two sets showed that they belonged to the same body. We fear it is too much to expect that further investigation will furnish evidence [illegible] of the remains, much less to the detection [illegible]

Digitized by Google

persons who compassed the death of the deceased—that is, supposing a murder was committed. The late inquiry has been the means of providing an opportunity for the careful study of a problem, which will, no doubt, not be lost sight of by those whose fortune it was to attempt its solution. We trust a careful record of the facts will be published.

UTILITARIAN JUSTIFICATION OF VIVISECTION.

IN another column we record the main outlines of a successful case of removal of a tumour from the brain. It may be well here to point out the chief steps in the process by which so desirable a result was enabled to be brought about. Certain symptoms running a definite course clearly pointed to disease of a particular portion of the cortex of one cerebral hemisphere. This is the main fact on which a discussion of the merits of vivisection on the the ground of utility must turn. Could we without the aid of experimental pathology have arrived at the precise regional diagnosis of the disease? The answer to that question must be given in the negative. No doubt clinical observation and careful post-mortem examination may effect a good deal; but hardly, however, in the direction of the initiation of accurate knowledge in the region of neural physiology and pathology. It is but seldom that nature acting in the guise of disease distinctly affects definite functions of the brain or spinal cord. Moreover, however much clinical and pathological work may have been able to effect, it yet remains as a patent fact that though hundreds of years have been spent in the acquisition of medical knowledge, it was not until Ferrier and Hitzig's experiments that anything like real knowledge was acquired on the subject of the localisation of functions in the cerebral cortex. It is not ten years since good physiologists refused to admit that different parts of the brain subserved different purposes. Experimental pathology may, in the region of the cerebral cortex, be said to have been a royal road to the acquisition of accurate knowledge.

ANOTHER DEATH FROM PATENT MEDICINES.

THE necessity for immediate legislative action in the matter of patent medicines is well illustrated by a sad and painful case of poisoning by chlorodyne which recently occurred at Weymouth. From the evidence given at the inquest it appears that the patient, a young lady of thirty-three or thereabouts, is well known to have been suffering for some years from religious monomania of an aggravated type. About six years ago she attempted to commit suicide by taking three ounces of chloral which she had obtained surreptitiously, and was only restored with the greatest difficulty after the application of remedies for over three hours. She was then certified as being of unsound mind, and was for a time confined in an asylum. For many months past her mental condition has been a source of constant anxiety to her friends and relatives, and it is known that she on various occasions threatened "to do something terrible," assigning as a reason that life was unendurable, and that she could no longer bear it. On Thursday, the 4th inst., she was missing from the house of a friend with whom she was staying, and two days later was discovered in a dying condition behind the bed in an empty room in her father's house. By her side was a glass which had evidently contained poison, and in a drawer near the bed, with her hat and gloves, were found three empty chlorodyne bottles, two large and one small. Treatment this time was unavailing, and in a short time she ceased to exist. A rigid inquiry was instituted, and at the inquest a chemist's assistant came forward and deposed that on November 13th he had sold her a 1*s.* 1½*d.* bottle of chlorodyne, and on the 19th a large 4*s.* 6*d.* bottle. Another chemist's assistant, with equal candour, affirmed that on the 20th of the same month he had supplied her with a 4*s.* 6*d.* bottle of the same drug; whilst a third chemist said he had done the same two days later. These gentlemen one and all admitted that they had sold these large quantities of chlorodyne over the counter without any inquiry; but one, on being asked if he would have supplied her with half-a-dozen bottles if she wanted them, demurred, and said it was a poisonous preparation. Another witness, however, had no such scruples, and admitted that he would have sold her a larger quantity if she had asked for it, "as it was a patent medicine." In the course of the inquiry it was stated that the composition of chlorodyne was well known, and that ten drachms, or about two tablespoonfuls, contained six drachms of chloroform, half a drachm of tincture of capsicum, three minims of oil of peppermint, eight grains of hydrochlorate of morphia, twelve minims of prussic acid (Scheele's, double strength), one drachm of tincture of Indian hemp, and one drachm of treacle. The maximum dose, according to the medical evidence, is about half a drachm, and it was calculated that a 4*s.* 6*d.* bottle contained enough to kill at least eight people. The jury, after a prolonged inquiry and careful deliberation, returned the following verdict:—"That this jury, having carefully considered the evidence generally, are of opinion that deceased died from the effects of chlorodyne which she administered personally during a fit of temporary insanity, and we desire strongly to urge that representation should be made to the proper quarter making it necessary that chlorodyne and other patent medicines of such a potent nature should be placed under Paragraph 2 of the Poisons Act." With this expression of opinion we most heartily concur.

MORTALITY AMONG METROPOLITAN IMBECILES.

THE mortality statistics of the Metropolitan Asylums for Imbeciles at Leavesden and Caterham are instructive from many points of view. Their most noticeable feature is, perhaps, their steady decline during the thirteen years since the institutions were brought into use. In 1871 the death-rate among the mean number of inmates in the two institutions (2844) was equal to 164·6 per 1000. No approach to so high a death-rate has occurred in any subsequent year, and the mean annual rate in the five years 1871–75 was 132·9 per 1000; in the next four years it fell to 85·6; and in the last four years, 1880–83, it further declined to 75·8. This marked decline in the mortality of these pauper imbeciles since they were transferred from the metropolitan workhouses to these special institutions suggests some unpleasant thoughts with regard to the condition of the 12,056 pauper lunatics and imbeciles who, according to the last report of the Lunacy Commissioners, are still retained in workhouses without any attempt being made to ensure trustworthy statistics of this helpless population. This remarkable reduction in the death-rate of the metropolitan imbeciles in recent years also throws much light upon the great apparent increase of lunacy in the metropolis, compared with the recorded increase in other parts of the country. To this part of the subject we shall recur. With regard to the mortality in the institutions at Leavesden and Caterham it may be noted that the mean annual rate in the thirteen years ending 1883 was 91·1 per 1000 at Leavesden and 110·6 at Caterham. The noticeable excess in the Caterham mortality was maintained until the end of 1881, but in both 1882 and 1883 the death-rate there fell to 66·3 and 64·2, considerably below the rates for those years at Leavesden, which had increased to 72·1 and 84·6. A word or two in conclusion upon the mortality statistics of the new asylum for adult imbeciles at Darenth, the institutions at Leavesden and Caterham having had a comparatively

Digitized by Google

stationary population of 4000 since the beginning of 1877. The Darenth adult asylum was opened in May, 1880, and the mean number of residents was respectively 220 in 1881, 320 in 1882, and 659 in 1883. The annual death-rate among these inmates averaged 126·7 per 1000 during these three years, whereas the mean death-rate in Leavesden and Caterham in that period did not exceed 75·9. It is evident that, as was the case when the Leavesden and Caterham institutions were opened, the health condition of the patients admitted at Darenth was very inferior to that of the patients who had for some time been residents in these metropolitan asylums. Trustworthy mortality statistics of lunatics and imbeciles in workhouses and residing with relatives, are urgently needed in refutation of the natural inference to be drawn from the remarkable statistics of the Metropolitan Asylums for Imbeciles. We recommend this subject as calling for the urgent attention of the Local Government Board and of the Lunacy Commissioners.

DR. RICHARDSON ON THE PAINLESS EXTINCTION OF LIFE OF THE LOWER ANIMALS.

DR. RICHARDSON'S lecture on his process of painless killing of the lower animals scores for science a magnificent success. As its author said in the closing passages of his discourse, science has now given to the inferior creation a blessing which she dare not give to man himself—painless death. At the Dogs' Home over 6000 dogs have during the past seven months slept their final sleep, knowing as little of their deaths as of their births. The principal agent used for the narcotic action is carbonic oxide, passing, at summer heat, over a mixture of chloroform and carbon bisulphide into a lethal chamber, in which chamber as many as 100 dogs can at once receive euthanasia. This is on the large scale; but Dr. Richardson described also a small apparatus which, after long trials, he has completed, in which from one to six animals can be painlessly killed, and which is so portable that it can be wheeled from a central station to any house or street ready for immediate use. Thus every village and town may be provided at a small cost with a means that will give painless death to any domestic animal without offending the most sensitive individual. By an extension of the same design the author next intends to apply it to animals of the larger kind that are used for human food, its application to the slaughtering of sheep being already quite feasible and inexpensive. By such works of beneficence as these man exerts his wisest and best dominion over natural sufferings and difficulties, and medicine is never more distinctly in her true position than when she is lending to that dominion the willing and practical aid which her representatives are specially fitted to confer. It is no contemptible part of its history in this century for the profession to leave as a bequest to the future the means of taking the sting of death from all our lower friends whose fate is under our control.

BACILLI IN SYPHILIS.

WE lately mentioned that Dr. Lustgarten had discovered a bacillus in syphilitic formations. This announcement has been speedily followed by a statement by Dr. Koniger (*Deutsch. Med. Wochenschrift*, No. 50) to the effect that in examining the sputa of certain cases of lung disease, where the tubercle bacilli were absent, he detected groups of long and delicate rod-shaped organisms differing in their staining reactions from the tubercle bacillus, and about twice as long as the latter. Two of the six cases in which these micro-organisms occurred were undoubtedly syphilitic, and further inquiry in two other of the cases showed that they also had been exposed to syphilitic infection. The fifth case was that of a [illegible] the history of having had many abortions, but the sixth case did not afford even these grounds for suspecting syphilis. The writer says he would have deferred mention of these cases until he had obtained larger experience had it not been for Lustgarten's discovery; and he believes that the detection of these bacilli in the sputum of a case of pulmonary disease may prove to be a sure test of its syphilitic nature.

H.R.H. PRINCESS CHRISTIAN AT THE MIDDLESEX HOSPITAL.

THE practical interest taken by the members of the Royal Family in the welfare of our great public charities was again evinced on Tuesday last in the visit to the Middlesex Hospital of H.R.H. the Princess Christian to open the new wing, a detailed description of which will be found in another column. Her Royal Highness, accompanied by Prince Christian, was received in the board-room of the hospital by Major Ross, M.P., chairman of the governing board, the members of the weekly board, and the medical staff, as well as a large number of ladies and gentlemen interested in the work of the hospital, including the Lord Mayor and Lady Mayoress, Lord and Lady [illegible], Lord George Hamilton, M.P., Mr. Coope, [illegible] and others. A contingent of the Volunteer Hospital Staff Corps formed the guard of honour, and the students of the hospital were engaged in the reception of the visitors, who lined the corridors of the building. Her Royal Highness was first conducted through the new wing, and on returning to the board-room a suitable [illegible] service, conducted by Bishop Tozer and the Rev. [illegible] Brindley, chaplain to the hospital, was held. This was followed by the presentation of an address to the Princess, who then declared the new wing open, and expressed her pleasure at having been present. It was stated in the address that one of the wards would, with Her Royal Highness's sanction, be named Helena Ward, and that Princess Christian had consented to be placed on the list of vice-presidents of the hospital. Purses to the amount of £400 were presented by ladies and children, after which Her Royal Highness inspected Queen and Helena Wards, accompanied by members of the medical and surgical staff.

"REASON OR INSTINCT."

UNDER this heading a simple narrative of [illegible] discussed at great length in the public press. The story was simple enough. A dog having received a wound in the foot went to Charing-cross Hospital apparently to be [illegible] treated. After demonstration of joy and gratitude when driven away, it returned to have the injured limb dressed. We see nothing in the story which either tends to [illegible] throws new light on the subject of instinct or on the power in animals below man. Those who believe that science teaches, that the only difference between the mind of man and that of his inferiors in the series of development is one of degree, can have no difficulty in understanding that these stories may all be true as the [illegible] undoubtedly is. There is really no distinction between reason and instinct. The one shades off into, and is part of, the other. Just as a dog remains to the [illegible] for food day after day, and is led [illegible] or shelter from outward appearance [illegible] scent, so a dog may very well [illegible] connecting that person with injured [illegible] lar building in pain, and come [illegible] this simple association of ideas this dog [illegible] the hospital and obtained what he [illegible] gone there he would go again. A dog [illegible] wash as well as to drink. A horse [illegible] likely place for a gallop. There is [illegible]

Digitized by Google

the lower animals possess mental powers which we call reasoning. It has been urged that the "doctors" at Charing-cross ought to have allowed the dog to remain as an "in-patient." The all-sufficient answer to this complaint is that the noise of the barking was disturbing to the patients.

OVER-PRESSURE IN SCHOOLS.

THERE is only one word more to say on this subject, and that had better be put into the form of a question. Is there to be an independent inquiry by an independent and skilled commission? So far as we can see, the policy of the Education Department is one of distraction and subterfuge. Beaten on the merits of the issue he had the enterprise to raise but not the moral courage to discuss impartially, Mr. Mundella is apparently resorting to the stale trick of riding away from the lists on a hobby arrayed in the trappings of a sentimental philanthropy. In the face of a demonstration that the children of the poor are being over-taught, the Vice-President has seized on the fact that part of the evil which results from over-pressure is due to the starved condition of the forced brains, and is now posing before the public as a benevolent supporter of penny dinners. Mr. Mundella may succeed in winning a little popularity by his patronage of the penny dinner movement, but, unless we are very much mistaken, he will not triumph in his main purpose, which is to divert public attention from the baneful effects of the system of competitive forcing in the culture of underbred, as well as underfed, brains. As physiologists we are persuaded that there is far too much haste in this educational movement as a whole. It must take several generations of evolutionary progress in the development of the average cerebral organism to produce brains which can be safely as well as successfully crammed as the empiricists of the Educational Department would have the brains of the million crammed to fulfil the requirement of "payment by results." Nothing short of an exhaustive inquiry can meet the needs of the case, and these must be met, and to the full.

THE ALTERABILITY OF CHLOROFORM.

IT is well known that the valuable agent chloroform is liable to undergo alterations if kept under ordinary conditions. M. Jules Regnauld has recently published the results of an investigation extending over a period of eighteen months. The effect of exposure to sunlight and air was to decompose chloroform, the decomposition occurring at the end of two days in July and of five in December. A similar result followed when the chloroform used had been previously saturated with water by agitation. The specimens of chloroform kept in the dark maintained their initial properties. If chloroform be in contact with oxygen and exposed to light decomposition takes place, but this is not the case if the atmosphere over the chloroform be pure nitrogen. These changes are independent of the presence of chloral. A very small proportion of ethylic alcohol in chloroform prevents the alterations which sunlight and air are able to effect. Toluene and allylic alcohol seem to have a similar preservative influence, which methylic alcohol, amylic alcohol, and benzene have not.

ZYMOTIC DISEASE IN MILE-END OLD TOWN.

THE chairman of the Sanitary Committee of Mile-end Old Town, in a letter to *The Times* on Wednesday last, gives an unqualified denial to the report of an outbreak of "fever" in that sanitary district of the metropolis. The statistics, however, by which this denial is supported are far from satisfactory. Comparison is made between the number of fever cases attended by the local medical officers during the three months ending 12th inst. and in the corresponding period of last year, but no reference is made to the cases of fever under treatment in the Metropolitan Asylum Hospitals. With reference to this omission, it may be noted that two fatal cases of enteric fever belonging to Mile-end Old Town were registered in those hospitals during the week ending 13th inst. If this fact were known to the local sanitary authority, why was all reference to it omitted from the chairman's letter? Then with regard to the claim for Mile-end Old Town "to hold its place of honour in the health reports of the metropolis," it appears from the letter in question to be mainly based upon the Medical Officer of Health's report for a single week ending November 29th (in which the deaths happen to have been fewer than in any recent week), and that without any correction for the deaths of Mile-end residents occurring in the Metropolitan Asylum Hospitals. During the week in question three fatal cases of small-pox and one of scarlet fever belonging to Mile-end Old Town were registered in these hospitals outside the district. Apart from the facts in dispute bearing upon the health of Mile-end Old Town, it is evident that the statistics put forward in *The Times* by the chairman of the local sanitary committee are worse than useless, being absolutely misleading.

WOOLWICH AND SANDHURST.

IN the reports of the Board of Visitors on the two great military schools for the year 1883–4, we are glad to observe a marked improvement in the information afforded regarding the health of the cadets, although we have still to regret that on that for Woolwich the average strength is omitted. If this were given, as it is for Sandhurst, and the number of days on which the cadets were in residence at both institutions were added, the returns of the medical officers would leave nothing to be desired. Assuming the numbers at Woolwich to have been 200, being the present limit of accommodation, and the period of residence as 264 days, the admissions into hospital have been in the *annual* ratio of 1227 per 1000 of the strength, and the number constantly sick 9·80 per 1000. At Sandhurst, where the average strength was 264, the number of days of residence being taken to be the same as at Woolwich, the admissions into hospital were in the ratio of 639, and the mean daily sick of 7·88 per 1000. The proportion of sickness at Woolwich therefore was nearly double that at Sandhurst, and the mean daily sick 1·92 per 1000 higher. The excess in the admissions into hospital at Woolwich has been due chiefly to three groups of cases—bronchitis and catarrh; dyspepsia, diarrhœa, and tonsillitis; and accidents and injuries. The disease in which this has been most marked is dyspepsia, of which only six cases were returned from Sandhurst, and 31 from Woolwich. This shows a remarkable change in the state of health at Woolwich compared with former years, for in 1880–81 there was not a single case of dyspepsia recorded, while at Sandhurst there were in that year no less than fifty-four cases (THE LANCET, Aug. 27th, 1881). The increase of hospital cases at Woolwich and the decrease at Sandhurst are deserving of inquiry as to their causes. The very high proportion of 1227 admissions per 1000 of the strength at Woolwich from a body of young men all of whom have been examined as to their physical fitness before admission into the Academy, appears to require some explanation. And this seems the more necessary as the Board of Visitors state that, "though not defective in physique, the countenances of the cadets generally looked pale and jaded," while at Sandhurst "the Board were much impressed with their muscular development and general healthy appearance." Is this difference to be accounted for by any marked difference in the sanitary condition of the two establishments or in their dietary, or may it be an effect of over-pressure of work in the one which does not exist in the other? The

Digitized by Google

subject deserves careful inquiry on the part of the military authorities, involving, as it does, the health of those whom we are training for military service, and the quality of the work they are called upon to do at the Academy; for there can be no doubt that this must be seriously affected by anything which deteriorates the health of the cadets.

PEACE-MAKING BY MACHINERY.

WE have received a communication describing at length a state of cheerless monotony and unsociability which is assumed to characterise the home life of the middle and lower classes of this country, and advocating freer intellectual and social intercourse among neighbouring families. The intention of the scheme is ostensibly good, its proposed method is certainly original and ingenious, but it may be doubted whether it is either necessary or judicious. It aims at the formation of "home dwellings of associated homes," and of "London and Provincial Societies of Conciliation and Reconciliation." In other words, we are to have more system and machinery introduced into social life; and such domestic and personal matters as voluntary seclusion from, or selection of intimate relations, abstinence from amusement on account of scruples or the *res angusta domi*, broken family peace and the like, shall be the concern, albeit as kind and as private as possible, of sympathetic committees of neighbours. While we may admit that a too strict abstention from pleasure has marred the happiness of some homes, has rendered sons or daughters unhappy or reckless, and has even been considered, not without reason, to have injured body or mind, and to have loosened by distrust the ties of morality which it was intended to confirm, we do not consider that this cause or this effect is usual, or that the scheme in question supplies an appropriate remedy. In the "association" of homes there is a degree of pushed acquaintanceship which savours rather of gregarious than of refined and social life. The intercourse of families cannot be undertaken or contracted for, nor should it be needlessly thwarted, but allowed to arise, as it naturally and usually does, out of the recognition of common interests. Conciliation, and especially reconciliation, is even less open to the offices—shall we say the officiousness?—of outside well-wishers. Mankind has long since agreed that matters of this most confidential kind cannot be guided by any official agency, but are best left in the keeping of those concerned, and of any to whose trusted delicacy they may voluntarily commit them. We cannot, therefore, do more than recognise the abstract benevolence of the scheme.

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES AT WIGAN.

AN improvement Bill is being promoted by the Corporation of Wigan, and it contains clauses compelling the householder and medical attendant to notify to the health officer the existence of infectious disease: a dual notification. The fee for medical attendant's certificate is fixed at 2*s.* 6*d.* At the ratepayers' meeting, however, opposition was raised to these clauses by Mr. W. M. Roocroft, and he was supported by Mr. Monks, J.P., the Chairman of the Sanitary Committee, both being members of the medical profession. The medical officer of health, Mr. Barnish, explained the reasons why he wished these powers, and he was supported by Mr. Councillor Berry. The meeting determined to retain the clauses, but a poll being demanded, the Sanitary Committee, on the recommendation of the Parliamentary Committee, have agreed to drop the clauses so that the town may be saved the expense of a poll. We would observe that unless more ample provision be made in Wigan for isolating infectious cases than at present exists, the compulsory powers would be deprived of much of their efficacy. The Sanitary Committee ought to see to this without delay, and put in force the powers they already possess under the Public Health Act.

COMMA BACILLI.

THE authorities of Genoa having placed a well-equipped laboratory at the disposal of Professor Antonio Ceci, he, with Professor Edwin Klebs, instituted a series of researches on the etiology of Asiatic cholera. *La Rivista Internazionale di Medicina e Chirurgia*, for last month, gives a preliminary report ("Communicazione Preventiva") of the joint research. Its results, so far as concerns the comma bacillus, do not accord with those of Professor Koch. The Genoa observers conclude, that comma bacilli are not invariably present in the fæces of cholera patients, or in the intestinal contents of the cadavers of those who have rapidly succumbed to the disease. They also failed to discover the comma bacillus in the air expired by patients in the algide stage of cholera; the blood of these subjects presented, under the microscope, no other morphological changes than increase in the number of white corpuscles, and deeper colouring of the red corpuscles due to cyanosis. The symptoms, death, and organic changes of individuals stricken with rapid cholera are not explicable by the slight lesions found in the intestine. In perfectly fresh cases, in which epithelium still existed *in situ*, no comma bacilli were found in the glands of Lieberkühn, although lymphatic cells abounded in the mucous membrane. So far as concerns their morphological characters, the comma bacilli and spirilli, of Asiatic cholera, proved identical with the comma bacilli and spirilli, obtained by Finkler and Prior of Bonn, from the culture of the fæces of cholera nostras patients. The same forms of spirilli were found by Klebs, in the diarrhœa of an individual suffering from pneumonia.

"PRESCRIBING SEPARATELY FOR EACH PATIENT."

IT seems that this mode of procedure is an offence to a certain order of minds which infests the board-rooms of unions and parishes. The guardians of St. Olave's are to be congratulated on having rejected the overture of members of their body to censure their medical officer, Dr. Smart, for adopting the method condemned. It is judged too costly to care for the needs of the poor individually even when the cause of need is disease. Being poor, they must be content to be physicked in classes, on the principle in force at Dotheboys Hall, where Mrs. Squeers administered brimstone-and-treacle to the scholars indiscriminately. Something like three or four mixtures (!) at most, and perhaps as many sorts of pills, would, in the estimation of certain officials, amply suffice for the "doctoring" of a whole population of paupers. Happily, not all are of this way of thinking, and some medical officers are independent enough to assert their professional right to practise the art of healing on rational principles.

THE LABOURERS ACT, IRELAND.

A QUESTION of great interest to dispensary medical officers in Ireland was decided last week in the Exchequer Division of the Court of Queen's Bench. It was the case of Dr. Rogers, of the Youghal Union, who brought an action against his Board of Guardians for services rendered—namely, for inspecting labourers' cottages, his bill including a sum of over £8 for car hire. The guardians refused the remuneration asked for on the ground that as medical officer of health he was bound to give those services gratuitously. The upshot of the trial, which, being a test case, was awaited with considerable interest, was that Dr. Rogers, having undertaken

Digitized by Google

the performance of duties which he might have declined, was not entitled to receive anything beyond his expenses for car hire. Very probably the matter will not be permitted to rest thus, and will be brought before another tribunal.

CHRISTMAS CHARITIES.

WE receive numerous appeals on behalf of various forms of Christian charity, and only regret we cannot make special mention of them individually. It would be well if for a few days, at least, starvation could be forgotten and "the hungry filled with good things." It should be the aim of every man, woman, and child who has the means, to see that the naked are clothed, and the cold warmed, and the downcast cheered. The special Christmas charities are, perhaps, not medical in their character, but they do good like a medicine. They cheer, they relieve, they revive, and restore. We would like to say a word, too, at this moment, to benevolent men and women in favour of the hospitals of London, in which six or seven thousand poor, and sick, and lamed will be lovingly and tenderly ministered to on Christmas Day, and all the other dark days of the winter. These institutions are amongst the most deserving of our charities; all the more that they are unsensational and unobtrusive.

SMALL-POX IN LONDON.

THE mortality from small-pox has steadily increased in the metropolis since the colder weather set in, the fatal cases during the past three weeks having numbered 40, 61, and 69 respectively. Following on a brief recurrence of milder weather there has been some reduction in the admissions into the hospitals of the Asylums Board, but everything seems to show that with severe weather a considerable increase in the number of attacks may be expected.

FOOTBALL.

THE following notice has been posted up at Harvard College: "The Committee on Athletics, having become convinced that the game of football as at present played by college teams is brutal, demoralising to players and to spectators, and extremely dangerous, propose to request the Faculty to prohibit the game after the close of the present season." We wish that some of those who control the sports of British youth would take steps to render this game less dangerous and objectionable.

THE BROWN LECTURES.

MR. VICTOR HORSLEY will conclude his series of lectures at the Brown Institution in Wandsworth-road, on December 22nd, at 3 P.M., by a demonstration of various tissues from the cases of artificial myxœdema and a practical exposition of the work of the institution.

"MEDICAL CHARGES AND DEATH CERTIFICATES."

IN our annotation under this heading of the 13th inst., we stated that the name of Mr. Burnes does not appear in the Medical Register. This statement was made in error; Mr. Burnes is duly registered, and we hasten to express our regret that the mistake should have occurred.

THE DEBATE ON CHARCOT'S DISEASE.

THE special meeting of the Clinical Society to which the debate on Charcot's Joint Disease has been adojurned, will take place on Tuesday, the 23rd inst., at 8.30 P.M., and not on the 19th, as previously arranged.

THE Committee on Organisation of the Ninth International Medical Congress, to be held in Washington, D.C., in 1887, met on the 29th ult., for the election of officers of the committee, who will be nominated to fill the same offices in the Congress. The following were appointed:—President: Dr. Austin Flint, Sen., of New York. Vice-Presidents: Dr. Alfred Stillé, of Philadelphia; Dr. Henry I. Bowditch, of Boston; Dr. R. P. Howard, of Montreal, Canada. Secretary-General: Dr. J. S. Billings, U.S. Army. Treasurer: Dr. J. M. Browne, U.S. Navy. The Executive Committee: The President, the Secretary-General, and the Treasurer, *ex-officiis*; Dr. I. Minis Hays, of Philadelphia; Dr. A. Jacobi, of New York; Dr. Christopher Johnston, of Baltimore; Dr. S. C. Busey, of Washington.

A PATHETIC STORY, entitled "It Won't Come Right," by F. S. J. B., is published by Wells, Gardener, Dunston, and Co., London. It illustrates the evils of brain-forcing, and shows how a poor little girl, eleven years old, was taught to death. The interesting feature in connexion with this work is that it was not written to support or express the views of Dr. Crichton Browne, having been actually in the hands of the printer before that report, which has attracted general attention, was made known.

THE second annual report of the Metropolitan Public Garden, Boulevard, and Playground Association has been recently published. It appears that during the past twelve months 85 new members have been elected, the total number of those belonging to the Association being now 214. Twenty-eight different matters have been taken in hand, and of these thirty have been carried to a successful ending.

A PHYSICIAN in the department of Maine et Loire is said to have at length discovered a means of overcoming the phylloxera by an easy and inexpensive treatment, the basis of which is an arsenical solution mixed with cinders. The limited experiments made with this preparation seem to have been attended with good results.

FOR some time past, small-pox has been raging at Trieste, an average of twenty five cases a day having occurred. The fatal cases are reported to be about twenty per cent. Several schools and other establishments have been closed by order of the authorities, and one of the schools has been converted into a hospital.

A PLUMBER in New York has recently been fined 250 dollars for having in a building he was erecting put in dummy vent-pipes and wash-basin traps, and fixed a dummy terminal on the roof, in such a manner as to be calculated to deceive the inspectors of the Board of Health.

ON the 14th inst., a steamship from Sfax arrived at Liverpool, having seven of the crew suffering from small-pox. The vessel was at once thoroughly disinfected and the sufferers removed to the infectious hospital.

THE latest news from Cairo contains the information that Dr. Sandwith has resigned his post in the Sanitary Department in Egypt.

EDWARD BELLAMY, F.R.C.S. Eng., has been elected Examiner in Surgery in the Victoria University, Manchester.

ASSOCIATION FOR PROMOTING A TEACHING UNIVERSITY FOR LONDON.

ON the 15th inst. a meeting was held at the house of the Society of Arts to discuss the report of the Subcommittee which was some time ago appointed to consider the best means for obtaining a teaching, instead of merely an examining, university for London. The committee, it was stated, embraced 163 names, and admitted of the following analysis:—Nine members of the Senate of the London University; the vice-president and eleven members of the Council of University College, and thirty professors; the principal and others representing King's College, and twenty professors; the Dean of Council (Professor Huxley, P.R.S.) and seven principal members of the teaching staff of the Science and Art Department, South Kensington; Lord Walsingham, trustee, the principal librarian, and four principal members of the staff of the British Museum; the principals of Manchester New College, the New College (South Hampstead), the Regent's-park College, the Queen's College for Women, the Finsbury Training College, and the Royal Academy of Music; the director of the City and Guilds of London Institute, the Dean of the College of Preceptors, the Head Masters of Westminster, University, and King's College Schools, and numerous representatives of the Council of Legal Education and their professors, of the General Council of Medical Education, of the Royal Colleges of Physicians and Surgeons, and of all the hospital schools, eleven in number.

After Lord Reay, who occupied the chair, had opened the proceedings, Lord Justice Fry moved the adoption, but afterwards the reception, of the report, which was taken as read, remarking that the great point was that there were bodies that were doing an amount of university teaching, and there were a number of scattered professors, but they had no connexion with the University of London, and the great object was to unite them with a university. No fault was found with the history or with the present condition of the University of London, which was admitted to have done a good work for education. The great question was whether they should endeavour to unite the scattered teaching, which if brought together would represent a creditable univereity, and it was this that was proposed by the approval of the report. Professor Frankland seconded the motion for the adoption of the report, and stated that the separate recommendations of the report might be subject to modification when they were discussed in detail, but he trusted that the scheme as a whole would substantially receive the sanction of all those interested in the education of the youth of the metropolis, and that there would thus be provided a veritable university training affording a real preparation for the performance of the duties of life and the true enjoyment of its pleasures.

Several speakers, including Dr. J. M. Duncan, the Rev. Dr. Wace, and Professor Ray Lankester, having questioned the prudence of at once passing a resolution to formally adopt a report, dealing with so many matters of delicacy and difficulty, in all its details, some of which required full consideration, Sir G. Young offered some explanations, in the course of which he said he did not suppose the meeting was in a position to pledge itself to every proposition in the report, and the adoption or reception of it would simply mean that it furnished a basis for subsequent deliberation and negotiation. All that would be affirmed substantially was the desirability of associating university teaching with university examination, and of conferring a voice in the government upon those who were engaged in teaching and in examinations. It was impossible to arrive at a teaching university without a close alliance with existing institutions. It was impossible to ignore the University of London until it had refused to co-operate with this movement. It was from the teachers in London that the support of this movement must come. The control of the teaching bodies was largely in the hands of amateurs or of educational statesmen, who could not be expected to advance with the times in matters of educational reform. London was formerly in the van; but now Oxford and Cambridge were distinctly ahead of it in many respects, and the colleges which ought to be the University of London were not able to appeal to the intelligence of the people of London, the colleges were stinted for the lack of funds, which might be forthcoming if they could appeal to the public in the form of a [illegible] Funds might be obtained shortly from sources no[t] available, and London might hope to have a te[ach]versity of which it would be proud.

Lord Justice Fry then said he proposed to alter t[he] of his motion, and to move that the report be recei[ved] the further consideration of it adjourned to a future [day]. After some remarks from Dr. W. Carpenter, [Canon] Church, Mr. J. Marshall, and others, the resolu[tion] altered by the mover, was agreed to unanimously.

Report of the Subcommittee appointed Monday, N[ov.] 1884, to draw up a Plan for the Teaching Univ[ersity] accordance with the objects of the Association, a[s] as follows:—

1. The organisation of university teaching in London, in the form of a teaching university, with [faculties] of arts, science, medicine, and laws.

2. The association of university examination with university teaching, and direction of both by the authorities.

3. The conferring of a substantive voice in the go[vernment] of the university upon those engaged in the work of university teaching and examination.

4. Existing institutions in London, of universi[ty rank] not to be abolished or ignored, but to be taken as [the basis] or component parts of the university, and either [federated] completely incorporated, with the minimum of change.

5. An alliance to be established between the u[niversity] and the professional corporations, the Council of Education as representing the Inns of Court, and the Colleges of Physicians and Surgeons of London.

The following is the plan proposed by the Subc[ommittee] which consisted of Lord Reay, chairman; Profe[ssor] Marshall, F.R.S., Ex-P.R.C.S.; Dr. W. M. Ord, F[.R.S.]; Mr. F. Pollock, barrister-at-law; Mr. R. S. Poo[le] Museum; Dr. P. H. Pye-Smith, F.R.C.P.; Profe[ssor] W. Warr, King's College; Professor A. W. W[ard] University College; and Sir George Young.

A. THE CONSTITUTION OF THE TEACHING UNI[VERSITY].

To be founded on—(1) The faculties or constituent [colleges]; (2) a board of studies for each faculty; (3) a govern[ing body] or council.

1. *The Council.*

To consist of members representative of—(*a*) The faculties. The proportion of representatives of the to the whole number of the council to be at least [illegible]. (*b*) The Senate of the University of London. (*c*) The of Legal Education. (*d*) The Royal Colleges of P[hysicians] and Surgeons. (*e*) It should be a point for con[si]sideration whether other public bodies should be [rep]resented on the council—e.g., the authorities of the Museum, of the Royal Academy and Royal Society, Incorporated Law Society, and of the Institution of Engineers. (*f*) Colleges and other educational [institutions] associated with the university. The amount of [representa]tion and the qualification for direct representation on council to be determined in each case, having regard to the nature and the amount of the education [given] formed, by the associated institution. (*g*) Endowments, e.g., the Crown, if the teaching university should State endowment; the corporation and companies of London, if they contribute to endow the [university].

Representatives of associated institutions and [other] bodies not to exceed one-third of the whole number on the council.

3. *The Boards of Studies.*

To be elected by each faculty. Some additional [members] might be appointed by the council. The boards [to] all matters relating to the faculty, and to exercise in such matters as are delegated to it by the [council]. Facilities to be provided for joint meetings of two or more boards of studies, when necessary. The [council] appoint some or all of the representatives of the [faculties] the council. If any are appointed by the faculties they should also be ex-officio members of the [council].

3. *The Faculties.*

To consist for electing purposes of [illegible] professors, lecturers, or persons of [illegible] the colleges or educational institutions [illegible]

Digitized by Google

university. (*b*) Examiners for the time being in the teaching university and in the existing university. (*c*) Additional members, to be appointed by the council, on the recommendation of the board of studies. There might also be honorary members of faculties, including graduates in that faculty, of the teaching university; members of Convocation of the existing university according to their degrees; recipients of degrees *honoris causâ*, and so forth; such honorary members having the right to attend and vote only at a general meeting of the faculty, to be summoned on requisition when necessary.

B. RELATIONS OF THE TEACHING UNIVERSITY WITH OTHER BODIES.

1. *The Existing University.*

There might be one chancellor, with two vice-chancellors, the teaching university and existing university constituting one university in two departments. The degrees might, if necessary, be distinguished by their designation in some suitable manner. The senate of the existing university would remain unaltered, would be appointed as at present, and would control the present examinations and confer degrees, without interference. Convocation might accept the graduates of the teaching university as full members. The teaching university might, so far as is practicable, find a place of meeting at Burlington House, together with the existing university.

2. *The Professional Corporations.*

Degrees in law, medicine, and surgery to be recognised as qualifying *pro tanto* for call to the Bar or for licence to practise, the power of calling to the Bar or of conferring licences to practise being reserved to the existing authorities. The previous examinations of the teaching university to receive recognition by those authorities, such as is now given to the examinations of existing universities.

3. *Colleges, Educational Institutions, Special Schools, and Institutions for purposes of Research.*

Each associated institution to remain unaffected in any way, save in so far as it might be willing to adopt the recommendations of the University Council.

The School of Law of the four Inns of Court to be an associated institution, and its professors and examiners to be members of the Faculty of Law, but without further direct representation on the Council than that already given to the Council of Legal Education.

The recognised hospital schools of London to be associated institutions, and their professors and lecturers to be members of the Faculty of Medicine. The direct representation of the hospital schools on the Council being difficult, owing to their number, it might be provided that they should all have one representative, at least, on the Board of Studies of the Medical Faculty.

Schools of fine art and technical schools employing teachers, some of whom are not engaged in what can be called, strictly speaking, university work, if composing part of an associated institution, to be admissible as special schools of the university, and their principal teachers to be members of the appropriate faculties. Junior schools forming part of associated institutions to be admissible similarly as special normal schools for the purpose of training teachers. Institutions for purposes of research to be admissible as special schools, and their principals or principal members to be eligible as additional members of the appropriate faculty. Educational institutions, of which the work is either in kind or quantity insufficient to entitle them to rank as associated institutions, while at the same time partaking of a university character, to be similarly admissible as special schools.

C. WORK OF THE TEACHING UNIVERSITY.

The teaching university to obtain power to confer the usual degrees, either by way of supplemental charter to the University of London or otherwise, after such course of study and examination as may be determined on. As means and opportunity will allow, the teaching university to appoint professors in the more advanced studies, and for purposes of original research. The Council to negotiate with associated institutions for the increase of facilities for common attendance at lectures, laboratory work, and admission to libraries and museums, and for the concentration of teaching within one or more of such institutions, or within the university itself, in such studies as may appear desirable.

The extent to which it may be found possible to blend the examinations of the teaching university with those of the existing university, of the professional corporations, or of other examining bodies, to be determined hereafter, full liberty of action being reserved to the respective authorities.

Professors, lecturers, &c., who are members of the faculty, to have the title of " Professor, Lecturer, &c. (or on) " in the proposed university; the first blank denoting the college or institution with which they are connected, preceded by the title (if any) by which their chair or other office is known.

Students in associated institutions and special schools to be at liberty to become undergraduates in the teaching university, or to obtain degrees as at present from the existing university.

Signed on behalf of the Subcommittee,

6, Great Stanhope-street, Dec. 3rd, 1884. REAY, Chairman.

TREATMENT OF INTESTINAL OBSTRUCTION.

A DISCUSSION AT THE

LIVERPOOL MEDICAL INSTITUTION.

Dr. GEE, President, in the chair.

(*Concluded from p. 1065.*)

MR. PAUL said that one of the noticeable features of the debate was the comfortable manner in which physicians congratulated themselves upon their success in the treatment of intestinal obstruction. They warned us that one brilliant surgical success, or one post-mortem that showed how easily the obstruction might have been relieved, was likely to make an impression which would lead us to forget the number that recurred without surgical aid, or the number of post-mortems which showed that an operation could have been of no service. He presumed that five years was a fair average time to test the results of a particular medical practice. Well, for five years he had been pathologist at the Royal Infirmary, and during that time the records showed that twenty cases of intestinal obstruction had been admitted; of these, ten found their way into the post-mortem room, and a mortality of 50 per cent. could hardly be regarded as encouraging. Of the ten cases, three were slight bands in vigorous young subjects, one the same in an old man, one was a twist in a woman of fifty-one, two were concretions in the appendix cæci, one depended upon acute pelvic inflammation after confinement, one upon adhesions of the small intestine to a cancer of the rectum, and one upon fæcal accumulation, ulceration, and perforation in an old woman. Perhaps only the first three were really suitable for immediate operation; but he maintained that, notwithstanding what had been said as to the impossibility of making a diagnosis, most of the others might have been excluded by any surgeon who desired to select operation cases with particular care. The last three no one would have had any difficulty in deciding upon as unsuitable. Both of the two cases of ulceration of the appendix had symptoms of inflammatory trouble in the right iliac fossa, and though he would consider them quite suitable for an early operation, many surgeons would not. The case of twist in the woman of fifty-one and band in the old man would both have to be taken on general grounds—of age, constitution, &c.,—as both might have been relieved by operation if they could have borne it. What he wished to point out was that though the physician might not be able to say exactly what was the cause of obstruction in a case suitable for operation, he could very often discover grounds for not operating in unsuitable cases. Time only permitted a reference to one other point. In the course of his experience he had met with two or three cases of obstruction diagnosed to be due to cancer of the intestine, and in which the surgeon had refused to operate. A little consideration of the probable part attacked in this disease would almost invariably enable one to give relief by operation. He had notes of sixteen cases of cancer of the intestine, of which six were above the rectum. Of these, one was in the duodenum, one in the cæcum, one in the transverse colon, and three in the descending colon. Cancer in the duodenum came under the same clinical conditions as in the stomach; it was practically unknown in the rest of the small intestine. Fortunately, it

Digitized by Google

was very rare in the cæcum, and became more common towards the rectum. The rule should be that when the age and circumstances of the case pointed to obstruction by cancerous growth in the bowel, a right colotomy should be done in all cases where the growth could not be felt in the rectum. This would give relief in all but a very few, and could be followed, at the discretion of the operator, by an attempt at extirpation of the growth when the bowel was empty.

Dr. ALEXANDER was surprised not only at the paucity of successful cases described by previous speakers, but at the few cases of intestinal obstruction met with by anyone. He thought the backward state of the treatment of this disease arose from its occupying the debatable ground between the physician's department and the surgeon's department, so that physicians often kept the cases so long under unavailing medical treatment that the patients were moribund when the surgeon took charge, and then operation too often hastened the fatal issue. The few cases met with by single surgeons also prevented that continuous and prolonged study necessary to perfect the treatment. The cases should be handed over entirely to the surgeon, as he could carry out the medical treatment quite as well as the physician, and could prepare, on its failure, for prompt surgical treatment. In many cases it was possible to tell early in the case whether the ultimate recovery was probable or not. From the beginning in some cases the pinched face, weak pulse, and great prostration show that death is probably inevitable, and such cases should be operated on early. In operating, the intestines should not be disturbed more than necessary. A hand passed into the abdomen should explore the region of the vermiform appendage first, then the sigmoid flexure, and then the region of the transverse colon. In these three regions adhesive bands are found most frequently. When the constriction or tumour is found, it alone should be exposed. Death would occur in many healthy persons who had no obstruction of their abdominal contents were they treated as the descriptions show they had been treated. Aspiration in one case of obstruction from peritonitis saved the life of the patient, and in another case a foreign body had been removed by him with success.

Dr. RICH said that he would merely refer briefly to two points, one pathological, the other clinical. One reason why the differential diagnosis of this condition was so difficult depended upon the fact that within the abdominal cavity there were so many conditions predisposing to obstruction. And with reference to only one of these, the appendix vermiformis, which, as everyone knew, played a very important part in the causation of many obstructions, he might remark that the varietes of size and position of this little structure were apparently much greater than is generally imagined. Of thirty-five cases examined by him, in only fourteen did he find the appendix cæci normal according to the description given by Quain and other authorities. Many cases were regarded as obstruction which were merely examples of aggravated constipation. As a rule the symptoms speedily yielded to ordinary measures. There was one small detail of treatment which had not attracted the attention it deserved—viz., puncture of the bowel in cases of great flatulent distension. In several instances he had practised this with great benefit to the patient both in cases like those he had referred to and also in severe flatulent colic.

Dr. RAWDON could not help thinking that in future operative treatment would be more frequently resorted to in cases of intestinal obstruction, especially in cases where the symptoms came on suddenly and approached in character those of strangulated hernia. The chief difficulty, however, would be in the diagnosis. To give an instance of this: two years ago he attended an old lady with strongly marked symptoms of intestinal obstruction, even to the extent of repeated attacks of stercoraceous vomiting. In the end his patient recovered, and in ten days' time passed a gall-stone the size of a large walnut. There was one class of these cases of which he had seen three examples occurring in young children. He referred to intussusception where the diagnosis was comparatively easy; not only was there straining with the passing of bloody mucus, but the mass of invaginated bowel might often be felt high up through the rectum. In one case the intussuscepted gut was extruded through the anus for seven or eight inches. In the cases he had seen the inverted cæcum had always been the presenting part, several inches of the ileum with its mesentery having been forced through the ascending, transverse, and part of the descending colon. In the treatment of these cases he protested against the forcible injection of enemata of water or distension of the lower gut by air or gas. If left alone they might possibly recover by one or other of nature's processes, but not after such treatment. He was also opposed to abdominal section, on account of the difficulty in disengaging the invaginated bowel; or it might be impossible to effect this at all, not on account of adhesions, but because of the tight embrace of the outer layers of the bowel.

Dr. JAMES WILSON, while recognising the able manner in which this subject had been brought forward by Dr. Greves, contended that it was impossible to influence the small bowel by remedial measures from below, such as injection of air or fluid, inasmuch as the ileo-cæcal valve in a sound state will not admit of regurgitation of air or fluid. The only way in which the small bowel could be influenced would be (and this would be equally for evil as for good) by outward means through distension of the colon. For the same reason stercoraceous vomiting indicated that the obstruction was above the valve. In cases of intussusception he did not agree with opium being given in large doses, and he much questioned its utility at all, inasmuch as the opium diminished the peristaltic acton of the bowel, the very effort of nature to rid itself of the trouble; for what was the mechanism of intussusception if it was not from want of coördination of the circular and longitudinal muscular fibres of the intestine? If, therefore, by opium we succeeded in paralysing one or both sets of fibres, how could we hope to effect a cure? With regard to the question of operation, there was no doubt much to be said for and against. If operative measures were to be undertaken, they should be undertaken before the products of inflammation had become organised. No doubt it was very difficult at all times to decide upon the question, but much valuable time was often lost by useless (perhaps a worse word might be applied) remedies, and an operation decided upon when the most fitting step would be to send for the undertaker. In his hands electricity, both the interrupted and continued currents, had been very successful in cases of intussusception, and in a large class of cases coming under the head of paralysis of the muscular coat of the bowel, so often met with in adults and aged persons. He mentioned a case that occurred at the Worcester Infirmary under his care in which the obstruction had been complete for ten days and incomplete for a month, the patient being discharged quite cured; readmitted again, cured by the same means, and remained so nearly two years, dying eventually from cancer of the sigmoid flexure.

Dr. CRAWFORD narrated a case of intestinal obstruction which had occurred in his practice, and in which, after trying a number of remedies, including aspiration of the bowel, he ultimately succeeded in giving relief by forcible inflation through the rectum. He spoke strongly in favour of using the aspirator when the abdominal distension was great. He thought that in suitable cases gastrotomy should be performed.

Dr. ARCHER had found great relief follow the use of an aspirator needle in suitable cases, and mentioned one of cancer of the rectum, which derived great benefit from this simple procedure. He thought that it should be practised before undertaking any serious operation for intestinal obstruction. He called attention to the occurrence of obstruction in very fat people from fatty degeneration of the walls of the intestine, causing paralysis of the gut. He had seen two or three cases of this kind, and considered that one referred to by Dr. Waters and another by Dr. Carter might be classed under this head.

Mr. G. HAMILTON referred to two cases he had seen operated upon in Edinburgh, one of which recovered and one died. He spoke in favour of early laparotomy in acute cases.

INSANITARY HOUSES IN ST. GEORGE'S.—On the 11th inst. at the Thames Police-court the Sanitary Inspector of St. George's-in-the-East applied for an order under the Nuisances Removal Act enforcing the closure of twenty houses known as Perseverance-place. The inspector stated that in these houses there was no back ventilation or light; for the whole twenty only four closets were provided, and no provision had been made for children to use the waterclosets. Recently eleven cases of small-pox had occurred in these houses, and altogether they were unfit for human habitation. The order asked for was granted.

THE MIDDLESEX HOSPITAL.

DURING the past twelve months considerable alterations have been made in the Middlesex Hospital, involving a complete reconstruction of the out-patient department, the addition of a new dispensary and store-room, and the provision of further accommodation for officers, nurses, and servants. The necessity for these new buildings has long been felt, and the acquisition of some property adjoining the east wing of the hospital afforded an opportunity of supplying this need. For many years the increasing number of out-patients far exceeded the accommodation provided for them. The rooms in which the physicians and surgeons had to see patients were daily overcrowded to an unhealthy extent, whilst the waiting-rooms and dressing rooms for male and female patients were wholly insufficient for their purpose.

The new buildings are situated at the east end of the hospital, at the junction of Mortimer and Cleveland-streets. Reference to the annexed plan (drawn to a scale of 40 ft. to the inch) shows the arrangement of the ground floor. The building has a frontage of about 90 ft. in Mortimer-street, and 100 ft. in Cleveland-street, where it adjoins the Nursing Home. The entrance in the courtyard in front of the hospital is formed by a porte-cochère, to which vehicles containing patients can be driven, and opens into a corridor (T) which completely bisects the building, affording an exit for out-patients in Cleveland-street, guarded by a turnstile. At right angles to that corridor is another which runs the whole length of the building, opening into the main corridor of the hospital at one end and terminating at the other in a large stained glass window. The physicians' and surgeons' rooms open into these corridors along the west and south sides. The walls of the corridors are constructed of porcelain glazed bricks, and the floor of mosaic pavement. They are lighted from above by raised skylights, and the entrances and exits are protected against draught by swing doors.

As one enters the block from the main building the first room (A) on the right hand is for the medical cases. The room measures 20 ft. by 18 ft., and has opening out of it two dressing-rooms (B, C), each about 12 ft. by 8 ft., the one nearest the corridor being also fitted up for laryngoscopical examinations. Next in order, and opening from the entrance lobby, is a room (D) about 17 ft. by 13 ft., for the reception of urgent cases of illness and medical casual patients. This room is also provided with a dressing-room (E) lighted from the corridor. Immediately within the entrance is a small room (F) for the nurses in charge of the department. On the other side of the lobby, facing the medical casual room, is the surgery (G), a room 22 ft. long by 14 ft. wide, leading into a dress-

Digitized by Google

ing-room (I) eight feet wide. The surgery is intended for the reception of cases of accident and minor injuries, and the doors of both this room and of the medical casualty room are of sufficient size to admit of the passage of the ambulance in use at the hospital. Thus the ambulance can be taken into the porch, and the patient transferred immediately from the cab into either of the casualty rooms, and conveyed thence to any ward in the hospital, without further disturbance, by means of the hydraulic lift which was erected a few years ago. Passing through this dressing-room (I) we enter a large well-lighted room occupying the south-west angle of the wing, about 20 ft. square. This room (K) will be used by the assistant surgeons, and the assistant obstetric physician, for whose further requirements an examination room (L) has been fitted up. The room will also be used by the ophthalmic surgeon, in connexion with whose department there is in close proximity a dark chamber (H), 20 ft. long by 8 ft. wide, which is fitted with six lamps for ophthalmoscopic examinations. Room M on the south side will be furnished with a bed for the reception of any doubtful case of insensibility admitted in the night, and it is contemplated to fit up the adjacent room (N) as an electrical department. The room at the south-east corner is devoted to the medical and surgical registrars; it communicates by a special staircase with a muniment room in the basement. The rooms marked P and Q in the plan are fitted with benches as waiting-rooms for male and female patients respectively.

The dispensary occupies the rest of the space, and consists of the apartment R, about 40 ft. by 18 ft., arranged so as to allow of the dispensing for the in-patients to be carried on separately from that for the out-patients, the nurses having access to a window placed at the end of a lobby (V) leading from the main building. The delivery window for out-patients is close to the exit corridor. Contiguous to this is another room (S), 22 ft. by 10 ft., used as a store for lint, surgical dressings, &c., issued to the nurses through a window in the lobby above mentioned. Separating these two rooms is a small office for the senior dispenser, who is thus enabled to overlook both the departments. A staircase leads down from the dispensary into rooms of the same size underneath, which are fitted up as steam rooms for the preparation of decoctions, &c., with a tincture press and other apparatus, and also as a store for drugs. The area outside this part of the basement is furnished with a lift for heavy goods, and the cellars are utilised for the storage of spirits and other inflammable materials. There is also a hand-lift from the store to the dispensary. In the room S a still supplied with steam from the engine room enables a sufficient supply of distilled water to be conveyed direct to each of the three dispensing counters. We believe that great care has been taken in the arrangement of the various fittings in this department, so as to ensure complete and efficient supervision with the greatest economy of labour, and all who are interested in the details of hospital construction and management would do well to inspect it.

A portion of the remaining three floors is devoted to an extension of the nursing home, including a ward for sick nurses. Another part, perfectly distinct, is utilised as apartments for the house-steward and male servants, the topmost floor being fitted up as a private ward. The part of the building facing Mortimer-street forms a residence for two of the house-surgeons and the obstetric assistant, the new building replacing a house formerly used for this purpose which had become so dilapidated that it had to be taken down. A laboratory will be fitted up on the topmost floor of this house.

The whole block is heated throughout by hot water, and cisterns furnished with filters are reserved for the supply of drinking water which is conveyed to all parts of the building. Care has been taken that none of the water- or gas-pipes should be built into the walls, so as to be accessible in their whole extent, the various pipes being distinguished by being painted different colours. The waterclosets are of the pattern of Doulton's patent wash-out closet; those apportioned to the out-patients and male servants are worked by an automatic flushing apparatus. The soil pipes from these closets, and the pipes from the sinks, are conveyed immediately outside the buildings down the open courts (W W W), the method of ventilation adopted being that known as the open air interceptor system. The floors throughout are constructed of iron girders and concrete, thus rendering the building fireproof; and on the ground-floor and basement are kept fire-hose, buckets, &c. Teak has been used in the construction of the staircases, of the flooring of the two wards and the out-patient rooms. The rooms C E H are ventilated by Tobin's tubes. The architect is Mr. Matt. Wyatt, F.R.I.B.A., and the contractors, Messrs. Higgs and Hill.

MAHOMED MEMORIAL FUND.

DR. MAHOMED (Physician to the London Fever Hospital and Assistant-Physician to Guy's Hospital) succumbed to an attack of typhoid fever on November 22nd, at the early age of thirty-five. He was quite without private means, and having been thus cut off, almost at the outset of his professional career, his widow and five young children are left unprovided for. These facts, together with due consideration of the great services Dr. Mahomed rendered to the advancement of scientific medicine without regard to his own private pecuniary interest, induce his friends to make an appeal on behalf of those he has left behind.

It is earnestly hoped that this letter will meet with liberal and early response from the medical profession and from the friends of those institutions with which Dr. Mahomed was connected, and in his work for which he probably contracted his fatal illness. There must be many who would like thus to give substantial expression to their appreciation of his character and services.

At a meeting held at Guy's Hospital on December 10th, the following committee, with power to add to their number, was formed, in order to raise a memorial fund:—The Earl of Devon, President of the London Fever Hospital; Cardinal Manning; the President of the Royal College of Physicians; Sir William Gull; Sir James Paget; Sir Henry Acland; Dr. Paget, Regius Professor of Physic in the University of Cambridge; Sir Edwin Saunders; Dr. Habershon; Mr. Alderman Fowler, M.P., Treasurer London Fever Hospital; Professor Humphry; Dr. Wilson Fox; the President of Guy's Hospital; the Treasurer of Guy's Hospital; the Staff of Guy's Hospital and of its Medical School; the House-Surgeons and House-Physicians of Guy's Hospital; His Honour Judge Chalmers, Hon. Secretary to the London Fever Hospital; Thomas Hyde Hills, Esq.; John Hamer, Esq.; H. C. Burdett, Esq.; Dr. Hare; Dr. Chadwick; Dr. Husband; C. Macnamara, Esq.; Dr. W. E. Buck; Dr. Broadbent; Dr. Cayley; Dr. Grigg; G. P. Field, Esq.; Herbert Page, Esq.; Dr. Hughling-Jackson, F.R.S.; Dr. Andrew; Dr. Dyce Duckworth; Dr. Douglas Powell; Dr. Octavius Sturges; Dr. Withers Moore; Dr. Buzzard; Dr. Lauder Brunton, F.R.S.; Dr. Shepherd; Dr. Theodore Williams; Dr. Robert Barnes; Dr. Stephen Mackenzie; Dr. Sidney Coupland; Dr. Cleveland; Dr. Duffey; Dr. Donald Hood; Shirley Murphy, Esq.; C. A. Aikin, Esq.; Dr. J. M. Bright; Dr. Clifford Beale; F. Argles, Esq.; G. Eastes, Esq.; Dr. Markham Skerritt; and George Lawson, Esq.

The following further subscriptions have been received:—

Subscriptions will be received by the Treasurer, A. E. Durham, Esq., 82, Brook-street, Grosvenor-square, W.; or by the Secretaries, Dr. Goodhart, 25, Weymouth-street, Portland-place, W., and W. H. A. Jacobson, Esq., 41, Finsbury-square, E.C. The fund will remain open in case any contributors may wish to spread their subscription over a term of years.

WILLS OF MEDICAL MEN.

THE will of William Henry Sheehy, M.D., late of 39, Great Percy-street, Clerkenwell, who died on Oct. 24th last, was proved on the 19th ult. by Mr. William Henry Patmore Sheehy, the son, and Mrs. Sarah Sheehy, the widow, the executors, the value of the personal estate amounting to upwards of £10,000. The testator bequeaths £1000 to each of his children; and £200 to his brother Michael in America. The residue of his property is to be held upon trust for his wife for life or widowhood; and on her death or marriage again for his four children.

The Scotch Confirmation under seal of office of the Commissariot of Lanarkshire of the deed of settlement and codicils of James Patterson Cassells, M.D., late of 2, Newton-terrace, Glasgow, who died on April 13th last, granted to Mrs. Anne Bruce Murdoch or Cassells, the widow, has been sealed in London, the value of the personal estate in England and Scotland exceeding £7000.

The will of George Henry Marshall, M.D., F.R.C.S., formerly of 176, Broad-street, Birmingham, but late of 28, Tisbury-road, West Brighton, who died on July 31st last, was proved on the 1st ult. by Mr. John Mitchell Marshall and Mr. Henry F. Marshall, the sons, two of the executors, the value of the personal estate amounting to over £2900. The testator after making some specific bequests to his wife and to his said two sons, leaves the residue of his real and personal estate upon trust to pay the income to his wife for life, and then for his five sons in equal shares.

The will of Jeremiah Scott, M.R.C.S., late of Barnsley, Yorkshire, who died on August 25th last, has been proved at the Wakefield District Registry by Messrs. James Brown and Thomas James Newman, the executors, the value of the personal estate exceeding £1400. The testator gives £50 to his housekeeper, Hannah Gambles, £40 to Francis Scott, and the residue of his property to his mother, Mrs. A. Scott.

The will of Charles Marchant Jones, F.R.C.S., formerly of Amoy, China, but late of Plymouth, who died on May 16th last, has been proved at the Exeter District Registry by Mr. Allan Belfield Bone and Mr. John Stapleton Jeffreys, the executors, the value of the personal estate exceeding £2700. The testator leaves all his estate and effects upon trust for Matilda Isabella Wells.

The will of Cadwallader Brooke Wolseley, M.D., formerly of St. Helens, Dunfanaghy, Donegal, but late of Castleton, Northwich, Cheshire, who died on July 22nd last, has been proved at the Chester District Registry by Mrs. Katie Maria Wolseley, the widow and sole executrix, the value of the personal estate in the United Kingdom amounting to over £2700. The testator devises and bequeaths all his real and personal estate unto his wife absolutely.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. Graham Moore Robertson, of 21, Cleveland-square, Hyde-park, £250 each to St. Mary's Hospital, Paddington, the London Hospital, Whitechapel, and the Hospital for Sick Children, Great Ormond-street.—Mrs. Eliza Hatton, of Ivy House, York-road, Leeds, £150 to the Ilkley Hospital, and the residue of her property to four charitable institutions, of which the Leeds General Infirmary and Cookridge Hospital are two, either equally or in such parts as her executors may determine.—Mrs. Mary Anne Matilda Willoby, formerly of Brighton, but late of 4, Priory Garden-villas, Hastings, £2000 to the Hospital for Consumption and Diseases of the Chest, Fulham-road, and £1000 each to the Cancer Hospital, Fulham-road, and the Sussex County Hospital, Eastern-road, Brighton.—Mr. Eustratios Ralli, of 93, Lancaster-gate, and of Scio House, Putney Heath, £500 each to St. Mary's Hospital, Paddington, and the Royal Hospital for Incurables, Putney; and £500 to the hospitals of his native island of Scio.—Mrs. Ann Bean, of 166, Lewisham-road, £200 each to the Royal Kent Dispensary, the City of London Truss Society, the Seamen's Hospital at Greenwich, and the British Asylum for Incurables.—Mr. William Charles Jones, of Manchester, and of The Elms, near Warrington, Cheshire, £500 to St. Mark's Hospital, founded by Mr. Salmon; and £100 each to the Manchester Infirmary, the National Hospital for the Paralysed and Epileptic, and the Royal Hospital for Incurables.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5946 births and 3798 deaths were registered during the week ending the 13th inst. The annual death-rate in these towns, which had been equal to 20·9, 23·8, and 24·4 per 1000, declined again last week to 22·6. During the first eleven weeks of the current quarter the death-rate in these towns averaged 21·5 per 1000, against 21·2 and 21·1 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 15·8 in Huddersfield, 16·6 in Birkenhead and Wolverhampton, and 16·9 in Portsmouth. The rates in the other towns ranged upwards to 30·2 in Bolton, 31·2 in Blackburn, 32·4 in Cardiff, and 34·1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 396 and 392 in the previous two weeks, were 393 last week; these included 80 from measles, 75 from whooping-cough, 61 from scarlet fever, 60 from "fever" (principally enteric), 45 from small-pox, 37 from diphtheria, and 35 from diarrhœa. No death from any of these diseases was registered last week in Birkenhead; while they caused the highest death-rates in Cardiff, Bolton, and Preston. The greatest mortality from measles was recorded last week in Hull, Cardiff, Leicester, and Bolton; from scarlet fever in Brighton and Newcastle-upon-Tyne; from whooping-cough in Preston, and from "fever" in Halifax, Cardiff, and Derby. The 37 deaths from diphtheria in the twenty-eight towns included 27 in London and 4 in Salford. Small-pox caused 71 deaths in London and its outer ring of suburban districts, but not one in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had increased from 580 to 1027 in the preceding five weeks, were 1011 on Saturday last; the admissions, which had been 149, 228, and 263 in the previous three weeks, declined again to 190 last week. The Highgate Small-pox Hospital contained 92 patients on Saturday last, against numbers increasing from 18 to 80 in the previous five weeks; 22 cases were admitted last week, against 24 and 35 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 511 and 499 in the preceding two weeks, further declined to 457 last week, and were 97 below the corrected average. The causes of 106, or 2·8 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Derby, Blackburn, and in four other smaller towns. The largest proportions of uncertified deaths were registered last week in Oldham, Hull, and Sheffield.

Digitized by Google

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had rapidly increased from 22·3 to 31·8 per 1000 in the preceding four weeks, declined again to 28·3 in the week ending the 13th inst., but exceeded the mean rate during the same week in the twenty-eight large English towns by 5·7. The rates in the Scotch towns last week ranged from 17·9 and 19·5 in Greenock and Leith, to 32·6 in Glasgow and 36·6 in Paisley. The 684 deaths in the eight towns included 30 which were referred to whooping-cough, 27 to measles, 23 to diphtheria, 17 to diarrhœal diseases, 8 to "fever," and 4 to scarlet fever; in all, 109 deaths resulted from these principal zymotic diseases, against 101 and 140 in the preceding two weeks. These 109 deaths were equal to an annual rate of 4·5 per 1000, which was more than double the mean rate (2·2) from the same diseases last week in the twenty-eight English towns. The 30 deaths from whooping-cough included 11 in Glasgow and 4 in Greenock. Of the 27 fatal cases of measles 13 occurred in Glasgow and 10 in Dundee. The 23 deaths from diphtheria included 11 in Glasgow and 3 in Dundee. Five of the deaths from "fever," and all the 4 from scarlet fever, were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 181 and 231 in the two previous weeks, declined to 190 last week, but exceeded by 83 the number returned in the corresponding week of last year. The causes of 92, or more than 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 35·4 and 33·2 per 1000 in the preceding two weeks, further declined to 28·7 in the week ending the 13th inst. During the first eleven weeks of the current quarter the death-rate in the city averaged 29·3 per 1000; whereas the rate during the same period did not exceed 20·0 in London and 19·6 in Edinburgh. The 193 deaths in Dublin last week showed a further decline of 30 from the high numbers in recent weeks, and included 24 which were referred to the principal zymotic diseases, against 39, 23, and 25 in the preceding three weeks; 9 resulted from scarlet fever, 8 from whooping-cough, 3 from measles, 2 from "fever" (typus, enteric, or simple), 2 from diarrhœa, and not one either from small-pox or diphtheria. These 24 deaths were equal to an annual rate of 3·6 per 1000, the rate from the same diseases being but 2·2 in London and 1·5 in Edinburgh. The 9 deaths from scarlet fever corresponded with the number in the previous week, while the 8 from whooping-cough exceeded the number in any recent week. The fatal cases of measles, "fever," and diarrhœa showed a decline. No inquest case or death from violence was registered, while the 51 recorded in public institutions showed a further decline from recent weekly numbers. The deaths both of infants and of elderly persons also showed a decline. The causes of 26, or more than 13 per cent., of the deaths registered during the week were not certified.

MORTALITY IN THE PUNJAB.

Two recently received weekly returns, issued by the Sanitary Commissioner of the Punjab, afford most unsatisfactory evidence of the insanitary condition of that Indian province. It appears that during the fortnight ending Oct. 18th the annual death-rate in the province was equal to 73·7 per 1000. This terribly high death-rate was mainly due to mortality from "fever," to which no fewer than 39,755 of the 48,882 deaths from all causes were attributed. The deaths included 151 from small-pox, and but 3 from cholera. It is noteworthy that the death-rate in the forty-two large municipal towns of the province was 72·0 per 1000, and slightly below the rate for the entire province. It is evident, therefore, that the mortality in the rural parts of the province exceeds that in the largest towns. The "fever" fatality in some of the smaller towns is, however, sufficiently startling. In the week ending October 11th 175 deaths occurred in the town of Karnal, with a population of 23,133, giving an annual rate of 393 per 1000, 147 of the deaths being attributed to "fever"; the same number of deaths from "fever" occurred during the same week out of 185 deaths from all causes in the town of Umballa, with a population of 26,777 persons. Such death-rates from "fever" are almost beyond comprehension, and it would be well if we could believe them to be impossible.

THE REVIVAL OF OVARIOTOMY.

To the Editor of THE LANCET.

SIR,—The address on the revival of ovariotomy, which you did me the honour to insert, having been reprinted in pamphlet form, I have sent (and intend to send more) copies to some of my friends. In reply Mr. Nunn, Consulting-Surgeon to the Middlesex Hospital, has sent me a very interesting letter, with the suggestion that if I think it of sufficient importance I shall send it on to you for publication. I trust you will consider that it may be of such interest to your readers as to merit a place in your columns.

I am, Sir, yours truly,

T. SPENCER WELLS.

Upper Grosvenor-street, December 8th, 1884.

"DEAR SIR SPENCER WELLS,—I have to thank you for the copy of the 'address delivered at Birmingham.' It is of the greatest interest to all who have been engaged in ovariotomy as a history of your special work commenced at the Samaritan Hospital, and continued, one may say, over Europe; work which has resulted in giving a *rational and scientific basis* to the operation of ovariotomy. There was, however, a pre-Samaritan era of ovariotomy *in London*, of which I happen to have directly or indirectly some personal knowledge, and I write to you on this. The operation was then more or less an empirical proceeding, the propriety of which was warmly disputed. If you will refer to THE LANCET of 1847, vol. ii., p. 467, you will find a report of the meeting of the Westminster Medical Society, October 23rd. At that meeting Dr. F. Bird related a case of 'extirpation of both ovaries with recovery.' A discussion on ovariotomy followed. Mr. Francis Hird said that he '*doubted whether the operation was justified by the general result of cases of ovarian disease.*' Dr. Murphy, on the other hand, 'thought the fault was with the operator, and not with the operation.' Mr. Hancock made reference to the alleged suppression of the truth about fatal cases of ovariotomy. The following year I became the colleague of Dr. Frederick Bird at the Western Dispensary, Westminster, and I also made the acquaintance of Baker Brown, who at that time was with Samuel Lane, Alexander Ure, and others, working to establish St. Mary's Hospital, then in embryo. In THE LANCET of 1848, vol. i., p. 201, there is a report of a paper by Baker Brown (December 15th, 1847) giving the details of a case where, after much treatment by mercury and pressure, he came ultimately to suggest that Mr. Lane should perform ovariotomy.

"In a series of most able papers in THE LANCET, Dr. E. J. Tilt dealt with the question of ovarian disease. At page 420, vol. ii. (Oct. 14th, 1848), Dr. Tilt says:—'There are now 150 cases recorded, ... though insufficient for the final decision of the question of ovariotomy;' and at page 526 (Nov. 11th), he gives an analysis of the results of the operations of Lane, Bird, Walne, Jeaffreson, and Clay. It was just about this time that I joined the Westminster Medical Society, and became aware that the excitement of the somewhat acrimonious discussions on ovarian disease had not subsided. Baker Brown had vehemently assailed Dr. F. Bird, and advocated tapping and pressure. At the meeting of January 27th, 1847, Baker Brown exhibited bandages 'applicable in the treatment of ovarian dropsy'; one bandage 'applicable where pressure is required for a long time after tapping.' Now, Sir Charles Locock was a staunch friend of Baker Brown's, and sent to him cases of ovarian disease. Brown was kind enough to ask me to assist him in tapping such cases. I cannot tell you accurately the number of these, but at any rate they were sufficient to prove in many that tapping and pressure and mercury could be of no avail; that is to say, where sebaceous matter, hair, bone, and teeth (the, as it were, sweepings of a pathological dustbin) constituted the contents of the sac, to say nothing of a multilocular or semi-solid condition of the tumour. Thus it became obvious to Brown that his favourite plan had to be thrown overboard, and hence he began his career as an ovariotomist. I assisted him in his operations of ovariotomy, as I had done in his cases of tapping, until St. Mary's Hospital came into full blossom, when I almost lost sight of Brown, he obtaining assist-

Digitized by Google

ance (as was quite natural) from his colleagues at St. Mary's, and thus the matter went on for a time. However, Brown's operations for ovarian disease at St. Mary's Hospital were attended by results so unfortunate (I use the word advisedly as proper to the *empirical* stage of ovariotomy) that his colleagues objected to the further practice by him of ovariotomy at the hospital. I was told that he was even threatened with a coroner's inquest if he again operated with a fatal result. This was in the year before the *annus mirabilis* of ovariotomy, 1858, to wit. At this juncture Baker-Brown again came to me, and appealing to my past experience of ovariotomy, and to my conviction that it was a justifiable operation, proposed that we should establish a small hospital where it could be carried out. The upshot of this interview was the opening of the *London Home* in 1858, and we commenced operations there, *but practically on the old lines.* Although certain improvements of detail had been introduced, we were still groping in the dark; it was bewildering to see that whilst the most unpromising cases frequently did well, those apparently favourable died. Nélaton paid a visit to the London Home, and he did not conceal his astonishment when he was shown three or four cases recently operated on satisfactorily convalescent. The great French surgeon took care to inspect the cicatrix of the abdominal incision in each case. You will most probably remember the date of Nélaton's visit to London to study ovariotomy. I believe your first communication to the Medico-Chirurgical Society was on five cases of ovariotomy (1859), your second on fifty cases (1863), and then on five hundred, and soon increasingly distancing your competitors. This vast labour and your example, as I have said, have afforded a *rational and scientific basis* for an operation which formerly was a dread proceeding, and only attempted by a surgeon at the risk of being stigmatised as rash or unscrupulous. I cannot refrain from telling you that three years after you commenced to operate and the London Home was established, I (on Oct. 25th, 1861) read a paper at the Medical Society of the Middlesex Hospital on the subject of ovariotomy. At that date you had then operated (as you informed me) twenty-nine times, and Baker Brown had operated in the London Home nine times. I said in that paper that 'having during the past ten or twelve years assisted at some thirty cases of ovariotomy, I do not hesitate to say that I believe ovariotomy will take rank with the most approved surgical operations. I am quite sure that much of the mortality has been due to causes now preventable, and that by an increase of experience many former errors will be avoided, not only in the operation itself, but in the after-treatment.'

"Now, I say that I feel grateful to you, that by your unrivalled experience and *rational and scientific study* of the operation my prophecy has been more than fulfilled.

"I am, Sir, yours faithfully,

"Dec. 6th, 1884." "T. W. NUNN.

COCAINE.

To the Editor of THE LANCET.

SIR,—I have much pleasure in supporting the opinions of your many correspondents regarding the great value of cocaine, and in expressing the results of my experience of this most important drug as a local anæsthetic in ophthalmic surgery. Such is the high opinion I have formed of the value of cocaine, that I believe ophthalmic surgeons are as deeply indebted to Dr. Carl Koller for his discovery as the surgical world is to the late Sir James Simpson. I consider it specially valuable in ophthalmic surgery for the following reasons: its ease of application, its rapidity of action, its local effect only, its duration, and, lastly, its leaving no bad results. My experience leads me, however, to differ somewhat from those writers who are of opinion that it causes complete anæsthesia of the deeper structures of the orbit, so as to allow of enucleation. I am very sceptical regarding cocaine being sufficiently powerful to allow of this operation being performed without pain, and I would certainly hesitate to enucleate an eye by its use alone. I have been using it freely during the past month, and beg leave to report some of the more painful operations in which I employed it.

A foreman engineer had his right eye severely burned from an explosion of boiling metal, which resulted in symblepharon and destruction of a portion of the ocular conjunctiva at the inner angle of his right eye, laying bare the sclerotic, and thinning that membrane to such an extent that by focal illumination the retina could be seen. Preparatory to operating upon this case, for transplantation of conjunctiva from the rabbit, in company with Dr. Philip of this town and Dr. Crawford of Port Glasgow, a 4 per cent. solution of the muriate of cocaine was dropped into the eye. Eight minutes after the cornea and conjunctiva were as completely anæsthetised as they would have been under the influence of chloroform. Knowing the operation would last at least thirty minutes, the solution was dropped into the eye four times, at intervals of five minutes. The patient made no complaint of pain during the introduction of the eye-speculum, or while seizing the ocular conjunctiva with forceps, or in stitching the foreign conjunctiva to the newly rawed surface. But while dissecting and separating the cicatricial conjunctival bands he complained of pain, and asked for more drops to be put into his eye. After a further instillation of the solution the operation was finished, but not without some slight suffering. It was necessary during the operation to exercise care while applying the solution to avoid injuring the newly transplanted conjunctiva.

The next operation was on a young man aged twenty-six, who had a congenital malformation of both eyelids. There was in each eye a double eyelid with eyelashes. The inner eyelid of each eye was partly adhering to the cornea at its lower border. In the right eye there was a convergent strabismus. As in the former case, a 4 per cent. solution of cocaine was freely instilled into the cul-de-sac, and after an interval of thirty minutes the operation for strabismus was completed, without any complaint of pain. The solution was again applied, and we proceeded to remove the eyelid. During dissection there was no complaint of pain until the deeper tissues were reached, when the patient seemed to feel as much pain as if no anæsthetic had been used.

I may further mention that I have used it in the removal of cataract, and in such cases it is specially valuable during the removal of the lens, the cornea and conjunctiva being insensible to pain; spasm of the ocular muscles is prevented, and there is thus less risk of escape of vitreous.

In operations for iridectomy the iris does not become so completely anæsthetised as the cornea and conjunctiva. In strabismus operations pain is experienced during the hooking up and snipping through the tendon. Its value as a sedative in all painful eye affections is very great.

I remain, Sir, yours very truly,

N. GORDON CLUCKIE,

Greenock, Dec. 8th, 1884. Surgeon to the Eye Infirmary, Greenock.

To the Editor of THE LANCET.

SIR,—Perhaps during the present discussion on the merits of cocaine as an anæsthetic a brief series of experiments with a 10 per cent. and 20 per cent. solution of the hydrochlorate of cocaine may not be uninteresting, even to others than those engaged in my specialty in surgery. With the 10 per cent. solution I met with but very limited success, its highest merit being as a very partial obtander of pain. In one instance it gave some temporary relief in a case of chronic periostitis, whilst in the extraction of a tooth for a near relative, in whose case I had the opportunity of exhibiting the drug to the best advantage, the effects in preventing pain from the operation were almost *nil*. Without troubling you with similar examples, it may be said that the 10 per cent. solution is of but little use in odontalgia or neuralgia. The 20 per cent. solution gives much more promising results. I have instantaneously destroyed an exposed pulp—one of the most painful operations in surgery—almost without pain, the carious cavity having been so sensitive previous to the use of the cocaine that it could not bear the slightest touch; whilst I have extracted two permanent teeth without anything like the usual amount of pain, though in a third and severer case the relief was not so manifest, though sufficiently appreciable. Its action in a case of earache which incidentally came under my notice to-day was most striking. The severe pain seemed entirely relieved in a few minutes. My limited experience leads me to hope that with a stronger preparation, say 30 per cent., success will be greater, whilst it is not too much to say that extraction in children may be relieved of many of its horrors, though too much must not be

Digitized by Google

expected from its aid in the more difficult cases of extraction in adults. But the greatest achievement is the instantaneous destruction of an exposed pulp without pain, to the exclusion of the slow and painful method of destroying it by arsenious acid, &c. In three cases I have succeeded in almost completely reducing the acute sensibility of an exposed or partially exposed pulp, thus relieving dental surgery of one of its chief *opprobria*—the infliction of unavoidable suffering. With a stronger solution than that with which I have experimented it is fair to anticipate even more success, though of course the few examples I have brought before your notice must not be considered conclusive until more experience has been obtained. I had hoped to have worked upon more extended data, but the difficulty Messrs. Dinneford have experienced in obtaining the drug must be my excuse for any shortcomings in these few notes of my experience.—I am, Sir, yours faithfully,

HAMILTON CARTWRIGHT,
Professor of Dental Surgery, King's College.

London, Dec. 17th, 1884.

REFORM AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editor of THE LANCET.

SIR,—Perhaps it may be considered that the objects which the Association of Members of the Royal College of Surgeons has in view are of sufficient importance to warrant you in allotting a portion of your valuable space to a short letter on the subject.

This Association has only been in existence for a short time, yet it has received decided encouragement from those whose interests it has at heart; letters of approval and support have been received from all parts of the country; and the Ramsgate Medical Society has shown its interest in the undertaking by forwarding the following resolution:—"*That no alteration in the Charter of the Royal College of Surgeons would be deemed satisfactory by its Members unless it made provision for the Council being elected by the Members and Fellows unitedly.*"

The Association of Members of the Royal College of Surgeons in many respects approves of the recommendations and alterations proposed to be included in a new Charter of the College, which have been drawn up by a sub-committee of the Association of Fellows, passed at a general meeting of that Association, and submitted to the Council of the College.

It is hardly necessary to point out that the bulk of the revenue of the Royal College of Surgeons is derived from the fees paid by its *Members*. During the financial year ending in July, 1884, about £15,000 out of the total income of £20,000 was received in fees for the *Membership* examinations. The principle that taxation and representation should go hand-in-hand is so generally conceded that it is not unreasonable for Members of the Royal College of Surgeons to petition for a share in the management of the affairs of the College, to the maintenance of which they so largely contribute. The Association of Members therefore claims the right for Members of the Royal College of Surgeons to have representatives, elected by themselves out of their own ranks, upon the Council.

Until the Association of Members has had more time to ascertain the general opinion of Members of the Royal College of Surgeons as to the number of seats on the Council, which they may reasonably be entitled to claim, it can hardly be called upon to name any definite number. The Association desires, first of all, to establish the great principle that a large, educated and intelligent body of men should be permitted to have a voice in the management of an institution of which they may be said to constitute the backbone.

The objection has been raised that it would be impossible to ascertain by any system of voting the desires of the constituency that would thus be formed. It would, however, only be necessary that the system of election by voting papers should be adopted, which method is recommended by the Association of Fellows. The difference between taking the votes of 1000 and of 10,000 electors is only one of degree. The expenses of the election would not be great, and the Members of the College would probably be willing to defray them.

Knowing the ready manner in which you have always supported any movement which might be considered to be advantageous to the interests of the medical profession in general, we take the liberty of sending this short exposition of our views on the subject of medical reform.

We beg to subscribe ourselves, Sir, yours truly,

WARWICK STEEL,
J. NIELD COOK,
Hon. Secs. to the Association of Members of the Royal College of Surgeons.

3, New-inn, E.C., Dec. 16th, 1884.

AN ELECTRIC LARYNGOSCOPE: A WARNING.

To the Editor of THE LANCET.

SIR,—For several months past I have been engaged in conjunction with a young engineer, Mr. A. Vesey, and with a manufacturer of incandescent lamps and accumulators, Mr. C. H. F. Müller, of Hamburg, in Germany, in constructing a practically useful electric laryngoscope. As usual with inventions, the instrument constructed upon theoretical considerations has had to be subjected to several modifications, before being really useful. To-day, whilst we are still engaged in making these modifications, a commission agent called upon me, who had been advised to show me "a new electric laryngoscope." I was, of course, anxious to see it. What did it turn out to be? Nothing else than one of the later modifications of Mr. Müller's laryngoscopes, still in its original packings, the twin-sample of which was in my hall ready to be sent back to Germany as practically unsatisfactory. But whilst I had been charged for my specimen fifteen marks (fifteen shillings), the price demanded by the agent was no less than fifty shillings! Comment appears superfluous.

I am, Sir, yours obediently,

Welbeck-street, Dec. 1884. FELIX SEMON.

"MORBID RELIGIOUS AFFECTION."

To the Editor of THE LANCET.

SIR,—One of the most eminent of Scotch divines, the late Dr. Candlish, gives a strong confirmation to the view you have adopted and maintained in a recent notice on "Morbid Religious Affection." In his Exposition of the 1st Epistle of St. John, page 366, he writes:—

"Love, when its exclusive object is unseen, is sometimes apt to become ideal, shadowy, and merely sentimental. Even when God himself is, or is imagined to be, its object, it has not unfrequently taken that form and aspect. Meditative musing on the nature of God, the rapt gaze of solitary contemplation, the fixed eye of secluded devotion, filling itself with great thoughts of the divine majesty, excellency, and beauty, have had the effect of begetting in the soul a certain mingled emotion of solemn awe and melting tenderness, which is apt to pass for divine love. It is akin to the feeling which the hero or the victim of an affecting tale may call forth, though deeper far and more intense. In real life, in Church history, this kinship has been but too terribly exemplified. Love to God has been spiritualised and sublimated, as it were, into a passion; such a passion as may, and must, end in one of two ways: either in a sort of mystical and rapturous absorption of the human in the divine, or in a still more dangerous substitution of the human for the divine."

This testimony from a theologian of acknowledged ability and well acquainted with the workings of the human heart may afford a valuable contribution to your previous remarks.

Yours truly,

December, 1884. ARCHIPPUS.

"SHOOTINGS FOR LUNATIC ASYLUM PATIENTS."

To the Editor of THE LANCET.

SIR,—This novel method of treating insane patients, which appears to have been lately adopted at the Dumfries Lunatic Asylum, to which you call attention in THE LANCET of the 6th instant, demands more than a mere passing consideration; it will doubtless excite some interest, not unmingled with anxiety as to results, amongst members of the medical profession, the public, and the friends and relatives of the inmates, sane and insane.

The Scotch system is upon its trial at a critical period in

Digitized by Google

the history of lunacy practice, and it is of the utmost importance that its merits and demerits should be known speedily, for its justification, or otherwise, it will, apparently, be ere long necessary to place the results arrived at under it fairly and fully before the profession. Accurate statistics are called for, showing the total number of accidents, major and minor, occurring during a given period for which it can fairly be held responsible; the number of escapes, attended by accident or otherwise; the number of deaths by suicide and homicide; the proportion of attendants required to carry it out efficiently; and, lastly, it should especially be shown in what proportion, if any, the recoveries exceed those in English or other asylums. You rightly criticise the action taken by the trustees and directors of the institution in this matter; it is fairly open to question whether they are justified in so largely drawing upon the funds of a charitable institution as the leasehold or rental of some two or three thousand acres of land must entail for an object which can hardly be for the general good of the insane inmates, and which under the most favourable circumstances can only be participated in by an exceedingly limited number of them.

Most people will agree with your remarks that trustees and directors of endowed asylums should clearly keep before them the beneficent aims of original founders, and should not in any way be themselves the means of bringing an inquiry on themselves, such as has been the case in some other endowed charities.

I am, Sir, your obedient servant,

Dec. 13th, 1884. PARTIALLY OPEN DOORS.

SUCCESSFUL OPERATION FOR HERNIA IN A PATIENT WITH BRIGHT'S DISEASE.

To the Editor of THE LANCET.

SIR,—The following case may be deemed of sufficient interest for a place in THE LANCET. I must confess that I anticipated a very different result in a patient the subject of long-standing Bright's disease.

On Sept. 3rd, 1884, Thomas C——, aged sixty-eight, was admitted here suffering from chronic bronchitis and general dropsy. I found that his urine contained just one-third of albumen. Under treatment his bronchial symptoms were greatly relieved and the dropsy left him, but he remained very weak and anæmic and his urine unaltered. On Nov. 23rd he became the subject of strangulated femoral hernia. The symptoms were never urgent, nor the vomiting stercoraceous; but the taxis was unavailing. He could pass no flatus, his face assumed the anxious expression typical of abdominal mischief, and the tumour had become tender to the touch. On the afternoon of the next day (Nov. 24th) my colleague, Mr. W. Steer, gave the patient chloroform, and, with the assistance of Dr. Richmond Johnstone, I proceeded, with many misgivings for the ultimate result, to operate. In doing so I had to open the sac, which contained a knuckle of intestine only. The stricture was at the neck, and yielded to the edge of the knife with an audible snick. The patient passed flatus the same afternoon. On the third day the wound was again dressed with carbolised oil on lint, cotton-wool, and a splint. The sutures were taken out on the fifth day. On the eighth day the bowels were relieved for the first time in response to an enema, and again freely on the tenth day, when the wound was perfectly healed and the patient seemingly none the worse for his experience. The temperature, which was taken night and morning, never rose. The urine, which was tested on the day of operation, contained one-third of albumen.—Yours obediently,

R. J. SHEPHERD.

Rotherhithe Infirmary, S.E., Dec. 4th, 1884.

THE SUPERINTENDENTSHIP OF THE ABERDEEN LUNATIC ASYLUM.—Dr. Jamieson, one of the joint superintendents of this asylum, having, after forty years' service, expressed a wish to be relieved of the responsibility attaching to the senior officer, it has been decided that Dr. Jamieson's coadjutor, Dr. Reid, be appointed superintendent with full charge of the institution, and that Dr. Jamieson be appointed to the position of consulting physician with a salary of £300 per annum, and liberty to reside in the dwelling-house at Elmhill, rent free, during the pleasure of the managers.

ROME AND ITS WATER-SUPPLY.

(*From our own Correspondent.*)

THAT Rome has a water-supply the finest for purity and abundance in Christendom is a fact long accepted by European authorities, repeated in the latest English treatise on the sanitary state of the city, and confirmed by the elaborate series of analyses made recently by Prof. Mauro of Naples, assisted by Drs. Piccini and Nasini of Rome, and superintended by Prof. Cannizzaro of the Roman University. An incidental allusion to the fact in my letter of Sept. 29th seems to have wounded the sanitary *chauvinisme* of Dr. Sizer of Brooklyn, who prefers the Abana and Pharpar of Long Island to all the rivers of the Eternal City. He is welcome to his opinion, advanced as it is with the "glorious certainty" of youth, but may I ask him to let me retain my own and to hazard a few reasons for its retention.

First, however, I must clear the discussion of a few misrepresentations imported into it by Dr. Sizer. He makes me say that the Roman water-supply has been "long known for purity as the finest in Christendom." What I really said was that it was "the finest for purity and abundance in Christendom," therein agreeing with Dr. L. Aitken, who ("Sanitary State of Rome," London, 1881, p. 13) says:—"The water-supply is so good and so abundant that no city in the world comes near it in that respect. From the aqueducts alone it amounts to nearly 300 gallons daily for each inhabitant, and the waters do not come from contaminated rivers or lakes." Again, Dr. Sizer quotes me as saying that the Roman water "contains *only* 50 grammes per 100 litres of residue," and italicises "only" as if he had expected me to exclaim, "How is that for pure!" What I did say was that, when evaporated, it left a residue of "not more than 50 grammes to the 100 litres," implying that its solid residue was within the "limit of tolerance" allowed in drinking-water by the first authorities in Europe. I might have added "well within that limit;" but how was I to know that Dr. Sizer's notions of "purity" were so much more "peculiar" than mine, or that the standard of tolerance which is good enough for Hygeiopolis is not good enough for Brooklyn.

Another point, Dr. Sizer says, "In benighted America we should call such water unfit for drinking, unless our object was the speediest possible creation of calculi." Would he be surprised to learn from Wanklyn that water may contain 40 grains of solid residue per gallon, and yet be quite fit for domestic use? or that (according to the same authority) the water supplied to the University of Bonn, though containing 45 grains of solid residue per gallon, is yet good enough for drinking, because "organically pure?" Dr. Sizer thinks that in America the imbibition of such water would "create" calculi—that, in fact, Americans have only to drink enough of it to produce any amount of stone, and make the graveyards of the present the quarries of the future. Perhaps he is right. I can only say that in Europe we are built on other lines; that calculi, whether "constitutional" or "local," are exceptionally rare here; and that if he fathers them on the drinking-water, the "stones of Rome will rise in mutiny."

But referring Dr. Sizer to Buzzard's masterly treatise on "Diseases of the Nervous System," Lecture XV., for another theory of calculo-genesis, let me quote to him what Professor Cannizzaro says on the question of drinking-water:—"The chemist and hygienist may consider the following rules as established by statistics. Water may be held to be good for drinking when it is limpid; when it is free from noteworthy quantities of organic matter, especially of animal origin, and from ammonia; when, after evaporation, it leaves a residue not exceeding 50 grammes per 100 litres; when this residue yields no other salts but those of the alkalies and alkaline earths, nor more than 30 grammes of earth carbonates, nor more than 4 grammes of magnesia, nor more than 6 grammes of sulphuric anhydride corresponding to the sulphates. Now, the results of the analyses of our four great drinking-waters, set forth at ample length in this report, completely satisfy these conditions, and therefore confirm the ancient renown of the Roman waters for excellence. The best are the Acqua Marcia and the Acqua Vergine, the former having the advantage of a lower temperature. The Acqua Felice, although, like the other two, free from organic matters, may be considered as

Digitized by Google

inferior to them, since it contains a greater quantity of calcareous salts than the Vergine or the Marcia. The Acqua Paola, a mixture of the waters of the sources of Trajan and of that of the Lake Bracciano, although it yields less residue than the other three and has a smaller quantity of calcareous salts, and is therefore 'lighter,' must yet be regarded as inferior to the first two, because it contains a minute quantity of organic matter. This report puts on the same level of goodness the Marcia and the Vergine, notwithstanding that the composition of that minute quantity of solid matter they hold in solution is so different. They are, in fact, natural waters belonging to two different types, as their origins are different; in the Marcia the residue is almost all carbonate of lime proceeding from calcareous soils; in the Vergine the carbonate of lime is accompanied by quantities of silica and of alkaline salts, including those of potash, since this water is condensed and runs through separable volcanic soils.

While certain Italian and foreign physicians have by "trivial *a priori* reasoning" surmised that waters containing so much carbonate of lime as the Marcia favour the formation of vesical calculi, others assert that these waters promote the nutrition of the osseous tissues. On the other hand, some have suspected the potash salts in the Vergine to be injurious; some, again, think these salts and the other alkaline salts that accompany them to be beneficial. "Statistics," says Professor Canuizzaro, "justify neither the one set of opinions nor the other. The subject has been carefully examined by the River Pollution Commission, which, in its sixth report, has furnished proof that waters when they do not contain deleterious organic matters and leave no considerable residue are equally salubrious, whether the residue contains more or less carbonate of lime, or more or less alkaline salts."

Of the six tables in which Professor Mauro and his colleagues give the results of their analyses of the four drinking waters of Rome, I subjoin the fifth as indicating in grammes and referable to 100 litres of water, the weight of those components of which account should most be taken in judging waters, and for which therefore the value limits have been established by different authors and different commissions. Those adopted for this table are for the most part those of the Vienna Commission, which (says Professor Mauro) has shown itself the most exacting.

Per 100,000 parts of water.	Value: Limits.	Vergine.	Felice.	Paola.	Marcia.
Oxide of calcium, CaO	11—12	8·52	13·72	8·91	11·0
Oxide of magnesium, MgO	4·0	1·87	2·77	1·88	3·278
Anhydrous sulphuric acid, SO_3	2—6·3	1·702	2·036	2·09	0·264
Chlorine, Cl	0·2—0·8	1·283	1·001	3·728	0·89
Anhydrous nitric acid, N_2O_5	0·4	0·826	0·616	0·233	0·278
Anhydrous nitrous acid, N_2O_3	0—traces	Traces	Infinites. traces	0	0
Ammonia	0—traces	0	0.	Infinites. traces	0
Total residue dried at 180°	10—50	36·92	43·84	27·80	28·60
Total hardness expressed in French degrees	28—32	18·33	29·36	11·80	27·52
Quantity of oxygen consumed (Tidy's method). 3rd hour	0·05—0·25	0·0096	0·0064	0·0104	0·0082

As to the soil through which these waters descend from the Latian hills it would be difficult to find one better adapted for their oxidation. They filter down to the Roman Campagna through a mass of separable materials, constituting, hydrologically speaking, a kind of colossal sponge planted on the immense table of tufa and pozzolana. The engineer, Vescovali, has an eloquent passage on this subject, in which he has shown himself a master, but it is too long for quotation. Rather let me conclude with the tribute paid to the Roman water-supply by a great American man of letters who found residence in the Eternal City not the less attractive and beneficial from its water being "the finest for purity and abundance in Christendom." "The pleasant natural sound of falling water, not unlike that of a distant cascade in the forest, may be heard in many of the Roman streets and piazzas when the tumult of the city is hushed; for consuls, emperors, and popes, the great men of every age, have found no better way of immortalising their memories than by the shifting, indestructible, ever new, yet unchanging up-gush and downfall of water. They have written their names in that unstable element, and proved it a more durable record than brass or metal."

Rome, Dec. 6th.

PARIS.

(From our Paris Correspondent.)

THE NECROPSY OF M. MORIN.

WITH reference to the necropsy of M. Morin, reported in my letter of last week, I have further to communicate that in the removal of the larynx for more minute examination, Professor Brouardel discovered a most curious and unexpected phenomenon. It will be remembered that the bullet that struck Morin in the throat was found in the chest after having lodged for some time just above the left clavicle. The bullet in its passage wounded the left common carotid, and although the wound extended through all the coats of the latter, there was no sign of hæmorrhage either before or after death.

THE NEW ENTRIES.

At the last meeting of the Académie Council of Paris, Dr. Béclard, Dean of the Faculty of Medicine, read his report for the past year, from which it is shown that the number of medical students inscribed to October 15th, 1884, amounted to 3094, and that for the official year beginning at the above date there have been about 550 new inscriptions. The number of foreigners inscribed to December 1st, 1884, was 538, among whom there were 127 Americans, 96 Russians, 61 Roumanians, 52 Spaniards, 45 Turks, 30 Brazilians, 26 Swiss, 25 Greeks, 22 English. The number of lady students has considerably increased, for on Oct. 15th, 1884, the number amounted to 78, whereas on Oct. 15th, 1883, there were only 45. Twelve others have offered themselves as candidates, but have not yet been inscribed. Of the 78 already inscribed, there are only 13 French. The number of Russians amount to 47, English 11, and Americans 3. After the reading of the report, the question as to whether female students should be admitted to the "externat" and to the "internat" of hospitals was mooted, but no decision had been arrived at. The majority of the council, however, appeared inclined to admit them to the externat, but to exclude them from the internat.

THE CHOLERA EPIDEMIC.

This epidemic may now be considered at an end, as no fresh cases are reported to have occurred for more than a week, and it is to be hoped that we have heard the last of it.

December 17th.

THE SERVICES.

WAR OFFICE.—Grenadier Guards: Surgeon Horatio Robert Odo Cross, from the Medical Staff, to be Surgeon, vice A. L. Fernandes, retired.

YEOMANRY CAVALRY.—Leicestershire: Surgeon and Honorary Surgeon-Major Charles Morton Sidley resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the regiment on his retirement.

RIFLE VOLUNTEERS.—3rd Monmouthshire: Samuel Hopkins Steel, Gent., M.B., to be Acting Surgeon.—2nd Volunteer Battalion (the East Yorkshire Regiment): Lieutenant William Arthur Holmes resigns his commission; Acting Surgeon Arthur Henry Boissier resigns his appointment.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon B. Renshaw, to the *Defiance;* Surgeon C. L. Vasey, to the *Boscawen.*

THE BRITISH ASSOCIATION.—At the close of the British Association meeting at Montreal it was decided, in commemoration of the meeting and as a recognition of the hospitality with which the members of the Association had been treated in Canada, to form a fund for the purpose of founding a gold medal at the M'Gill University at Montreal. The medal will be given annually in the Faculty of applied Science, and a sum exceeding £500 has been collected, the interest of which will be applied for the purpose.

Obituary.

CHARLES OLIVES BAYLIS, M.D., M.R.C.S., L.S.A.

DR. BAYLIS, who only last year resigned the post of medical officer of health for West Kent, and who has since lived in retirement at Southport, died on Friday, Dec. 12th. On the following Tuesday his remains were brought to Birkenhead and interred in the parish church of St. Mary's. His funeral was largely attended, testifying to the estimation in which the deceased was held, and the flag at the Town Hall was hoisted half-mast high as a mark of respect for his memory.

Dr. Baylis was born in January, 1815, obtained a qualification in Edinburgh in 1837, and shortly afterwards commenced practice in Birkenhead. Here he received the appointment of surgeon to the Borough Hospital, and, after serving the institution for many years with acceptance, was made consulting surgeon. He was also elected an improvement commissioner, and in his position as chairman of the Health Committee laboured earnestly for the sanitary welfare of the town. About twenty years ago he retired from practice, and moved with his family to Douglas, Isle of Man; but in July, 1866, he returned to Birkenhead as medical officer of health, the post having become vacant by the appointment of Dr. Robinson to a similar position at Leeds. Dr. Baylis remained at Birkenhead, devoting his whole time to the duties of his office, till August, 1873, when he was made first medical officer of health for the now combined sanitary district of West Kent. During the spring of 1883 Dr. Baylis, owing to ill health, resigned his post, and, after a brief stay in the south of France, removed to Southport. The rest and sea air did not bring him relief. Disease of the prostate, from which he had long suffered, was followed by an apoplectic seizure, and this was followed by paralysis agitans. On the 6th he fell, going upstairs in his own house, and since then gradually sank. Dr. Baylis leaves a widow, two sons, and one daughter.

Medical News.

UNIVERSITY OF LONDON.—The following candidates have passed the recent M.D. Examination :—

Beverley, John Metcalfe, Manchester Royal Infirmary.
Roddy, Hugh Walter, Manchester Royal School of Medicine.
*Chesne, John Howard, Guy's Hospital.
Day, John Climenson, London Hospital.
*Haliburton, William Dobinson, B.Sc., University College.
Hipd, Wheelton, B.S., Guy's Hospital.
Hoole, Henry, Charing-cross Hospital.
Martin, Sidney Harris Cox, B.S., University College.
Murray, Hubert Montague, University College.
Pasteur, William, University College.
Pratt, Reginald, University College.
Rogerson, John Thomas, B.S., Manchester Royal Infirmary and University College.
Roughton, Edmund Williamson (gold medal), St. Barth's. Hosp.
Silk, John Frederick William, King's College.
Webb, Malcolm, Manchester Royal Infirmary.
Wilkinson, William Camac, B.A., Sydney, University College.

LOGIC AND PSYCHOLOGY ONLY.

Spicer, Robert Henry Scanes, B.Sc., St. Mary's Hospital.
Worthington, Sidney, Guy's Hospital.

*Obtained the number of marks qualifying for the Medal.

The following candidates have passed the recent M.B. Examination for Honours :—

MEDICINE.

FIRST CLASS.

Thorburn, William, B.Sc. (Scholarship and Gold Medal), Owens College and Manchester Royal Infirmary.
Turner, Alfred Jefferis (Gold Medal), University College.
Purslow, Charles Edwin, Birmingham School of Medicine.
Jones, J. Harvey, Owens College and Manchester Royal Infirmary.
Bushworth, Frank, St. Bartholomew's Hospital.
Prideaux, Frances Helen, London School of Medicine for Women and Royal Free Hospital.

SECOND CLASS.

Gostling, William Ayton, B.Sc., University College.
Powell, John Joseph, University College.
Eq. { Bennett, Frederick William, Owens College and Manchester Royal Infirmary.
Eq. { Cockey, Edmund Percival, St. Mary's Hospital.

THIRD CLASS.

Spencer, Herbert Ritchie, University College.
Glover, John Philip, St. Thomas's Hospital.

OBSTETRIC MEDICINE.

FIRST CLASS.

Lewers, A. H. Nicholson (Scholarship and Gold Medal), University College.
Thorburn, William (Gold Medal), Owens College and Manchester Royal Infirmary.
Prideaux, Frances Helen, London School of Medicine for Women and Royal Free Hospital.
Powell, John Joseph, University College.
Bushworth, Frank, St. Bartholomew's Hospital.

SECOND CLASS.

Gostling, William Ayton, University College.
Crookshank, Edgar March, King's College.
Anderson, George Elliott Caldwell, Guy's Hospital.
Dent, Harry Lord Richards, King's College.

THIRD CLASS.

Thomas, John Reglan, St. Bartholomew's Hospital.

FORENSIC MEDICINE.

FIRST CLASS.

Cockey, Edmund Percival (Scholarship and Gold Medal) St. Mary's Hospital.
Turner, Alfred Jefferis (Gold Medal), University College.

SECOND CLASS.

Reynolds, Ernest Septimus, Owens College and Manchester Royal Infirmary.
Eq. { Anderson, George Elliott Caldwell, Guy's Hospital.
Eq. { Prideaux, Frances Helen, London School of Medicine for Women and Royal Free Hospital.
Thorburn, W., Owens College and Manchester Royal Infirmary.

THIRD CLASS.

Lewers, Arthur Hamilton Nicholson, University College.
Day, John Roberson, University College.
Powell, John Joseph, University College.

The following have passed the recent B.S. Examination :—

FIRST DIVISION.

Bowes, William Henry, Guy's Hospital.
Collier, Joseph, Owens College and Manchester Royal Infirmary.
Elgood, Charles Reginald, University College.
Gostling, William Ayton, B Sc., University College.
Gross, Charles, Guy's Hospital.
Hewer, Joseph Langton, St. Bartholomew's Hospital.
Prideaux, Frances Helen, London School of Medicine and Royal Free Hospital.
Spencer, Herbert Ritchie, University College.
Thorburn, W, B.Sc., Owens Coll. and Manchester Roy. Infirm.

SECOND DIVISION.

Anderson, George Elliott Caldwell, Guy's Hospital.
Cooper, George Frederick, St. Thomas's Hospital.
Davies, William Thomas Frederick, Guy's Hospital.
Hartley, Robert Nightingale, Leeds School of Medicine.
Laurent, Eugène Arthur, University College.
Parry-Jones, Maurice, Guy's Hospital.

The following candidates have passed the recent B.S. Examination for Honours :—

SURGERY.

FIRST CLASS.

Collier, Joseph (Scholarship and Gold Medal), Owens College and Manchester Royal Infirmary.
Thorburn, William, B Sc. (Gold Medal), Owens College and Manchester Royal Infirmary.

SECOND CLASS.

Eq. { Gostling, William Ayton, B Sc., University College.
Eq. { Spencer, Herbert Ritchie, University College.

THIRD CLASS.

Prideaux, Frances Helen, London School of Medicine and Royal Free Hospital.
Hewer, Joseph Langton, St. Bartholomew's Hospital.

CAMBRIDGE UNIVERSITY.—At a congregation held on the 15th inst., the following degrees were conferred :—

BACHELOR OF MEDICINE.—Francis James Warwick, non-collegiate.
BACHELOR OF SURGERY.—Walter Dowson, Christ's.

COLLEGE OF PHYSICIANS IN IRELAND.—At the December Examinations the following obtained the licences in Medicine and Midwifery of the College :—

MEDICINE.—Patrick Duff, Martin Fennelly, C. Jackson, Cornelius Ignatius Kelly, Graham Egerton Kennedy, Charles Edmond Lister, John Joseph McDonnell, Thomas George Millerick, Andrew Murphy, Llewellyn Thomas Manly Nash, Jane Harriett Walker.

MIDWIFERY.—Martin Fennelly, Charles Jackson, Cornelius I. Kelly, Graham E. Kennedy, Charles Edmond Lister, J. Joseph McDonnell, Llewellyn Manly Nash, Francis Howard Sinclair, Jane H. Walker.

The undermentioned was admitted a Member :—

Joseph John Lamprey.

Digitized by Google

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Sciences and Practice of Medicine, and received certificates to practise, on Dec. 11th:—

Adams, Charles Edmund, St. Bartholomew's Hospital.
Baker, George Henry, Charing-cross Hospital.
Dipleck, Leonard Bramah, St. George's Hospital.
Hartley, George Thomas, Leeds School of Medicine.
Lewis, Percy George, King's College.
Spreat, John Henry, St. Bartholomew's Hospital.
Wrigley, Robert, St. Bartholomew's Hospital.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Charles Albert Adams, Charing-cross Hospital; James Young, St. Bartholomew's Hospital.

[In the pass-list of the Apothecaries' Hall published last week, Mr. W. A. H. Barrett is described as a student of St. Thomas's; it should have been "Westminster Hospital."]

THE Library of the Royal Medical and Chirurgical Society will be closed on Dec. 25th, 26th, and 27th.

THE MILLER MEMORIAL HOSPITAL at Greenwich was formally opened on the 17th inst. by the Lord Mayor.

DR. HART has been elected without opposition coroner for the Southern Division of the County Kerry.

NEW Hospitals are to be erected at Cairns and Maryborough, Queensland.

THE JACKSONIAN PRIZE.—Essays for this prize must be sent in to the Secretary of the College on or before Wednesday, the 31st inst., and not later than four o'clock.

BELFAST ROYAL HOSPITAL BAZAAR.—It is believed that a sum exceeding £3000 has been obtained by the recent bazaar and fancy fair held in aid of the funds of this Charity.

THE Leicester Branch of the St. John Ambulance Association has presented an ambulance waggon to the Corporation of that town.

THE Local Government Board have refused to sanction payments of money by the Canterbury Town Council to persons who had made claims for compensation for loss of work through discontinuing to take in tailoring and washing while infectious disease was present in their houses. The medical officer had directed these persons not to take in work while disease existed, so that infection should not spread, and it was thought that the Local Government Board would allow compensation.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At the monthly meeting of this Association on the 11th inst. Mr. J. S. Hodgson, Vice-President of the Manchester Architectural Association, read a paper on sewage farms, in which he stated that these farms were the only effective means of disposing of the sewage of large towns, and advocated the intermittent downward filtration system. The paper was followed by a discussion in which the Chairman (Mr. Vacher), Dr. Samelson, and others took part.

THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—On the 14th inst. an influentially attended meeting was held at Brighton, under the auspices of the board of management of this hospital, in reference to completing the Duke of Albany's memorial building and to consider a proposal to allot beds in the new hospital to the county of Sussex and Brighton. The proposal was warmly adopted, addresses in support of it being delivered by Dr. Crichton Browne, Dr. Tuke, and others.

THAMES VALLEY DRAINAGE.—The Local Government Board inquiry as to the proposed dissolution of the Lower Thames Valley Main Sewerage Board, or the separation from it of some of the constituent authorities, was continued at Kingston-on-Thames on the 13th inst. It was stated on behalf of the Richmond Rural Sanitary Authority that that body did not desire the dissolution of the joint Board or separation from it, and, further, that they were opposed to the proposed union of the urban and rural authorities in the matter of an independent scheme of sewage disposal for the five parishes comprised within the Richmond Poor-law Union. A number of witnesses were examined in opposition to the Richmond case, and the inquiry was again adjourned. The Works and Parliamentary Committee of the Main Sewerage Board have drawn up their report, which has been printed, and will be discussed at a special meeting of the Board to-day (Saturday).

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.

ANDERSON, Jas. FISHER, L.R.C.P., L.R.C.S.Ed., has been appointed Government Medical Officer and Public Vaccinator for Uranda, New South Wales.

BAINSLEY, THOS. BOOTH, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Tattenhall District of the Tarvin Union, vice Proudlove, deceased.

CALDER, ROBERT, M.B., C.M.Aberd., has been appointed Government Medical Officer and Vaccinator for the District of Brisbane Water, New South Wales.

CRESSWELL, THOS. HOBBS, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Grassington and Kettlewell Districts, Skipton Union, vice Anthony, resigned.

EMMERSON, WM. LINDSAY, M.D.Aberd., L.R.C.S.Ed., L.S.A.Lond., has been reappointed Public Analyst for the Borough of Stamford.

FITZMAURICE, RICHARD, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Third District of the Cuckfield Union, vice Porter, resigned.

GILDON, GEO. GORE, M.B., C.M.Glasg. has been appointed one of the Medical Officers to the Wellington Hospital, New Zealand.

GIVAN, JOSEPH, L.F.P.S.Glas., L.A.H.Dub., has been appointed Medical Officer to the Ballygawley Dispensary, Clogher Union.

HOLYOAKE, RALPH, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Hanbury District of the Droitwich Union, vice Roden, resigned.

JONES, T. W. CARMALT, M.A.Camb., F.R.C.S.Ed., has been appointed Surgeon to the Western Ophthalmic Hospital, vice Percy S. Jakins, resigned.

KEY, A. COOPER, M.R.C.P., L.M.Ed., L.S.A.Lond., has been appointed Physician to the Home of the Good Shepherd, Elsenham-street, Belgrave-square.

NICHOLSON, GERALD, M.R.C.S., L.R.C.P.Ed., has been appointed House-Surgeon to the Royal Cornwall Infirmary, vice E. Roberts, M.R.C.S., resigned.

PATERSON, WM. BROMFIELD, F.R.C.S.(cross), L.D.S., has been appointed Dental Surgeon to St. Bartholomew's Hospital.

ROBINSON, LOUIS, M.R.C.S., L.S.A.Lond., has been appointed Senior House-Surgeon to the Darlington Hospital, vice Dr. Hern, resigned.

STAPLE, JAMES D., L.S.A.Lond., has been appointed Assistant House-Surgeon to the South Devon and East Cornwall Hospital, Plymouth.

STEWART, ANDREW, L.R.C.P. & L.M.Ed., L.R.C.S. & L.M.Ed., has been appointed Medical Officer to No. 4 District of the Birkenhead Union, vice R. S. Daniel, deceased.

TURNER, GEO. JOHN KERR, M.B., C.M.Aberd., has been elected Surgeon to the Wadebridge Branch of the Ancient Order of Foresters and Western Provident Association; and has been appointed Medical Officer and Public Vaccinator to the No. 1 District of the St. Columb Major Union, vice Enifford, deceased.

WELCH, ROBERT, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer to the Workhouse, Southampton Incorporation, vice Bencroft, deceased.

Births, Marriages, and Deaths.

BIRTHS.

BARCROFT.—On the 5th inst., at Constantinople, the wife of Pearson J. Barcroft, Surgeon, R.N., of a son.

CLARKE.—On the 15th inst., at Fordwych-road, West Hampstead, N.W., the wife of Fincastle G. B. Clarke, M.D., of a son.

GODSON.—On the 11th inst., at Grosvenor-street, W., the wife of Clement Godson, M.D., of a son.

GRAVELY.—On the 18th inst., at Holmlea, Newick, Sussex, the wife of Frank Gravely, M.R.C.S., of a son.

ORR.—On Dec. 14th, at Worlaston, Wellingborough, the wife of James W. Orr of a daughter.

MARRIAGES.

SMITH—WESTON.—On the 11th inst., at St. John's, West Chelsea, James Murray Smith, M.B., C.M.Aberd., of Romford, youngest son of the late Alex. Smith, M.D., Forfar, to Beatrice S. Weston, daughter of the late James Weston.

DEATHS.

BAYLIS.—On the 12th inst., at 62, Windsor-road, Southport, Lancashire, Charles Olives Baylis, M.D.Aberd., M.R.C.S., &c., late Medical Officer of Health for West Kent, and formerly of Birkenhead, much loved and deeply lamented, aged 69.

BROWN.—On the 6th ult., on board the s.s. *Cognac*, off Accra, West Africa, Percy Brown, M.B., youngest son of the late Thomas Brown, M.R.C.S., of Finsbury-circus.

HANSON.—At his residence, 12, South Parade, Huddersfield, after a short illness, John Edward Hanson, M.D., C.M. St. Andrews, L.R.C.P.Lond., aged 33.

HUTCHINSON.—At The Elms, Bishop Auckland, on the 16th inst., Valentine Hutchinson, M.D., M.R.C.S.Eng., L.S.A.Lond.

MUSCROFT.—On the 5th inst., at Pontefract, Henry Muscroft, M.D., in the 55th year of his age.

SNAPE.—On the 13th inst., at Rodney-street, Liverpool, George Henry Snape, M.R.C.S., aged 40.

WASHBOURN.—On the 11th inst., at his residence, Ashmeade House, Gloucester, Thomas Buchanan Washbourn, M.D.Lond., F.R.C.P., aged 55.

WILLS.—On the 8th inst., at Thorncombe, Dorset, John S. Wills, M.R.C.S., in his 59th year.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the Journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE GROWTH OF "THE LANCET."

THE LANCET of the present week consists of 104 pages. In 1874 the corresponding number contained 64 pages, thus showing an increase in size of 40 pages in ten years.

TARTAR ON THE TEETH.

A.W.S., M.B., C.M. Ed.—There can be no doubt that "tartar," or salivary calculus, is chiefly due to inefficient brushing of the teeth. People do not half brush their teeth. They take great care to polish the fronts of the upper and lower incisors, but they seldom attend to the inside of the lower incisors or the outside and grinding surfaces of the molars; and the majority of people use tooth-brushes which are too soft. On the other hand, it is not to be understood that even efficient brushing will remove all tartar; for in certain conditions the normal saline constituents of the saliva are much increased, and where an alkaline reaction exists there tartar is most deposited. This contraindicates the use of soda, whilst the use of any active acid would be injurious to the teeth. The rational treatment of tartar seems to be: (1) its complete removal by suitable instruments, leaving no nuclei for fresh deposits; (2) the use of twenty drops each of glycerine, carbolic acid, and tannin in the water when brushing the teeth, adding a few drops of eau-de-Cologne; (3) the systematic and careful brushing of the insides as well as the outsides of the teeth, and (4) the occasional use of a carbolic tooth-powder, being careful to use plenty of water afterwards, to prevent accumulation of the powder between and around the teeth.

"IRRITATION OF THE SKIN FOLLOWING THE APPLICATION OF VASELINE AS A SURGICAL DRESSING."

To the Editor of THE LANCET.

SIR,—Will you kindly allow me space to endeavour to remove an unpleasant impression which has spread rather widely in consequence of a letter which appeared in THE LANCET of the 22nd ult. from the Chesebrough Manufacturing Company respecting the vaseline supplied by them to the Leeds Infirmary.

Passing over the very strong language used by them, for which they have since expressed to me their regret, I have to say that when their representative called upon me for an order he submitted three sample tins of vaseline, the prices being, I think, 9*d.*, 6*d.*, and 4*d.* per lb. He recommended the quality at 6*d.*, saying that they were selling tons of it a week to the large hospitals in London and the provinces, at the same time naming several of the larger ones in London which were using it. But he did not then, nor at any time, say that it was "sold for use on animals only," and I never heard the word "veterinary" used in connexion with vaseline of any description until I saw it used by the Chesebrough Manufacturing Company in their letter referred to above. This representative assured me that the "red" was equally as pure as the higher priced vaseline, and to demonstrate the fact he ate some of it in my presence. Besides, the material has always been invoiced to us as "red" vaseline, and not "veterinary." Further, it is a fact that the firm received our orders and executed them without ever once informing me that we were being supplied with a material which they say is "only made to be used on beasts."

I have already communicated these facts to the Chesebrough Manufacturing Company, and now leave them with the numerous readers of your journal. I would only add that to me the experience gained by this transaction will be of the highest service. Thanking you in anticipation of your valuable assistance.

I am, Sir, your obedient servant,

Leeds Infirmary, Dec. 8th, 1884. THOS. BLAIR, General Manager.

THE CANINE PATIENT AT THE CHARING-CROSS HOSPITAL.

WE learn that nothing has been seen of the dog since the morning of Wednesday the 10th inst., when he attended at the hospital at an early hour, with his bandage still on, walked round the place, and then strolled out. As to whose property he is, or whom he resides, the hospital authorities appear to have no information whatever.

C. H. A. M.—The law does not attach a penalty to attendance, but to the assumption of a name or title implying legal qualification.

ADULTERATION OF DRUGS.

To the Editor of THE LANCET.

SIR,—As a constant reader of THE LANCET I am sensible of belonging to a class which through various reasons frequently affords you the opportunity of comment, implying both censure and mistrust; and seeing that in your last issue you have given prominence to matters which vitally affect the reputation of every practising chemist and druggist, and have expressed your opinion thereupon without qualification, I must appeal to your sense of justice to allow a voice to be raised on the other side.

In your annotation on the adulteration of drugs you have deduced certain arguments from a report issued by the Local Government Board, under exceptionally misleading conditions. According to the analysts' returns, the total number of samples (of all kinds) examined was 19,648; of these 252 only were submitted to the analysts by private purchasers, or about 1·5 per cent. of the whole. The analyses of "drugs" were 304; and as it is fair to presume that the proportion of private purchasers of drugs would not greatly exceed those in other departments, probably no more than six samples from this source were reported upon. From such incomplete testimony it can scarcely be a correct assumption that "once in four times, upon an average, a prescription made up at a chemist's shop is not compounded of pure drugs prepared in strict accordance with the directions of the British Pharmacopœia." Again, where is the evidence to prove that these samples of drugs, or even the majority of them, were purchased from registered chemists? It is well known that drugs and pharmaceutical preparations of all kinds are sold by grocers, drapers, oilmen, and general dealers. I myself have seen some of these which were certainly not prepared strictly in accordance with the British Pharmacopœia. Is it at all unlikely that some portion of the samples examined were derived from sources of this description?

To that portion of the article which imparts to every chemist a knowledge of the existence of a state of affairs which, if true, would entitle him to eminence in the ranks of assassins, I, as a chemist in actual business, most strongly protest; and, with your permission, I would earnestly appeal to your readers as to whether they have found the substitution of cheap for expensive drugs a matter of common occurrence. With the Pharmaceutical Society on the one hand, and the British Pharmaceutical Conference on the other, coupled with a host of minor institutions, all working more or less in conjunction for the elevation of pharmacy, and for the advancement of every interest connected with it, whose members consist principally of pharmacists practising in every part of the United Kingdom, it is scarcely possible that such disgraceful practices could occur without frequent exposure. Such cases have, happily, been most uncommon, and I cannot remember a single recent instance where substitution has been proved.

It is easy, perhaps, to say that such an article as the one in question is of a general character, and that individuals must not be too prone to reduce it to the unit of effect; but what is the position of the pharmacist when confronted with accusations in a medical publication which to those technically unacquainted with his business he has but feeble opportunities of proving untrue? Debarred from the devices which are common to ordinary traders, excluded from the consideration which falls to the share of strictly professional men, there are hundreds of pharmacists working with one common aim to the advancement of all things pharmaceutical, with instincts as purely professional, and acknowledgements as distinctly ethereal, as many of those whose privilege it is to work in wider and higher spheres. I could wish for no better judges than those who are your ordinary readers, and to these I fearlessly appeal. If they are prepared to endorse your testimony, the labour of many years has been a wasted effort, and medicine owes nothing to pharmacy or the pharmacist.

I am, Sir, most respectfully yours,

CHARLES B. ALLEN,
Kilburn, N.W., Dec. 15th, 1884. Pharmaceutical Chemist.

Idem.—Our correspondent's letter seems to have been mislaid. We should be glad if he would repeat his question.

AN APPEAL.

To the Editor of THE LANCET.

SIR,—I am anxious to get some books and old periodicals for my patients in an infectious diseases hospital, as during convalescence time hangs very heavy on their hands; also for the workmen in a large sugar factory here, where a library and reading-room has been formed in the works. My own resources being now exhausted, if any of your readers will kindly forward me any old surplus stock of a readable, instructive and amusing kind, for which they have no further use themselves, I shall be only too pleased to acknowledge their receipt, and distribute them to the two places I have mentioned.—Yours respectfully,

Hack-road, Victoria-docks, E., Dec. 15th, 1884. JOHN MOIR.

EXAMINATION OF ARMY SURGEONS.

QUESTIONS FOR THE EXAMINATION OF SURGEONS-MAJOR.

First Day.

1. State, as briefly as you can, the principal objects aimed at by the present system of medical organisation and field hospital service.
2. Describe the lines of medical assistance in the field, traced from the front to the base of operations.
3. State the powers of an officer commanding a detachment of the Medical Staff Corps who deals summarily with a soldier's offence.
4. How are courts-martial on men of the Medical Staff Corps constituted, and by what authority are they convened?
5. What branches of the Service are responsible for the maintenance of buildings, and for the equipment and supply of hospitals in peace and war?
6. What are the principal points to be attended to in the medical examination of recruits?
7. What are the chief points to which attention should be paid in making a medical inspection of a ship taken up by the Admiralty for the conveyance of troops?
8. Briefly enumerate some of the more common and dangerous defects to be met with in an insanitary house.

Second Day.

9. How would you proceed to establish the insanity of a soldier, and fulfil the requirements of the law, previous to his admission to a lunatic asylum?
10. If called upon as a sanitary officer to advise as to the occupation of any given locality as a standing camp for a division of all arms of the service, what limit would you lay down as to density of population per acre?
11. State how long you think a camp, whether of huts or tents, may be continuously occupied; why its sanitary condition should gradually deteriorate, and in what way this deterioration might be expected to manifest itself as regards the camp population.
12. A force is going up the Nile in boats, ten to twelve men in a boat, and is required to carry provisions to last for 100 days, say; such provisions must be in the most compressed and portable form, and as varied as practicable; you cannot depend on any regular local supplies *en route*. State what articles of diet, &c. you would advise to be taken in each boat. You are not required to give the quantities.
13. What is your opinion of the utility of filters on active service in a tropical or semi-tropical climate? To what extent do you think a force could be supplied with filtered water under such circumstances? Are you in favour of having a filter as part of a soldier's water-bottle, or of giving a separate pocket filter to each soldier; and, if so, how would you propose to cleanse or renew the filtering medium?
14. You have a number of wounded men and amputation cases; the buildings available are, in your opinion, not at all adapted for the accommodation of such cases, and your tentage is deficient, but you have sufficient transport, partly wheeled, partly dhoolies, and bearers. What will you do with the wounded? How will you dress the wounds? What steps will you take to secure proper attention to them and to the other requirements of your patients? It is fine weather.
15. If called upon to report as to the water-supply of any given locality in which it is proposed to encamp a force of any given strength, how would you proceed to estimate approximately the quality and sufficiency of the available sources of supply?
16. You are sent to investigate into the causes of an outbreak of enteric fever in a small garrison or institution; briefly indicate the heads and steps of your inquiry.

THE ORAL EXAMINATIONS AT CAMBRIDGE.

To the Editor of THE LANCET.

SIR,—May I trespass on your space in order to mention a grievance to which examinees at Cambridge are subjected?

It is the custom here to allow anybody to hear the oral examinations, and it is this which I write to protest against. Of course, it does not matter in the least to men whose *robur et æs triplex* shield them from nervousness. But I have no doubt that many of your readers will be conscious of the state they were in when they had to undergo the ordeal of their oral examination; and to a man who is inclined to be nervous it is a terrible thing to see men he knows giggling and laughing about the nibblings he or others who went in before him may have made. I will venture to assert that this nervousness has been instrumental in plucking men, and that not infrequently. The only possible reason for this public examination is that it is intended to show future examinees what sort of thing they are to prepare for. Against this I submit (1) that the examination is for those who are examined at the time, not for those who are to be examined in the future; (2) that the majority of men, at all events of those who were present at the oral examinations this last [illegible] the examinations and therefore make them unduly [illegible] the people who ought to be the [illegible] and [illegible]

[illegible]

NERVOUS.

THE DISCUSSION ON INTESTINAL OBSTRUCTION IN LIVERPOOL.

To the Editor of THE LANCET.

SIR,—I was unable to take part in the above discussion at the Liverpool Medical Institution; but your faithful report of it has given me an opportunity of drawing attention to a point which I should not like allowed to pass unnoticed had I qualified myself to speak by sending notice.

Mr. Mitchell Banks, in adverting to the difficulties in connexion with the question of operation, mentioned as one the fact of spontaneous recovery under opium and starvation treatment, "which," he said, "had for many years been the recognised practice." I need hardly say that the latter remark took me greatly by surprise. Although I was a young member of the profession, I can recall the fact that in the [illegible] this form of treatment being recognised in my student days. We [illegible] professed to appreciate the value of opium neutralised by [illegible] giving milk, while others taught that calomel, enemata, [illegible] were the means and methods to which to look for escaping [illegible] words of Dr. Waters, who immediately preceded Mr. Banks in the discussion, could not have reminded him more forcibly that [illegible] to which he alluded had yet to be received by his fellow [illegible] Nor was his the only opinion in the same direction. The opium treatment was even condemned by some, enemata, &c. advocated, [illegible] and the number of those who adhered to the principles as laid down by the originator of this plan of treatment were very few. The explanation is evident. The opium and starvation treatment, [illegible] is not even known or understood by those who have not made themselves acquainted with its originator through his work on the subject. The treatment of intestinal obstruction by rest, opium, and starvation was undoubtedly originated by Mr. H. O. Thomas, and we require no further proof of its non-recognition generally, even at the present day, than the fact that it is not even alluded to by Mr. Treves in his new and exhaustive work. Nor do I think Mr. Banks can refer us to any writings that will justify his statement, although I am quite prepared to apologise and retract if he will.

I enter this protest against Mr. Banks's attitude with all [illegible] feeling sure that upon reflection he will agree with me that [illegible] able remarks were deprived of a finish which would have [illegible] them had he but rendered honour to whom honour was due.

I am, Sir, yours faithfully,

Liverpool, Dec. 8th, 1884. CHARLES [illegible]

To the Editor of THE LANCET.

SIR,—In your report of the recent discussion which [illegible] the Liverpool Medical Institution, on Intestinal Obstruction, I was very much astonished to read the following in Mr. [illegible]: "The second difficulty consisted in the fact of spontaneous recovery under the opium, rest, and starvation treatment, which had for many years been the recognised treatment." Is [illegible] and others of your readers if Mr. Banks would [illegible] authority for this assertion. I have read the Jacksonian [illegible] on this subject, and find no reference to the trinitarian [illegible] rest, and starvation, or, to speak more correctly, [illegible] tion, as the other two include rest to the bowel.

I am, Sir, yours, [illegible]

Dec. 8th, 1884.

To the Editor of THE LANCET.

SIR,—Last week's issue of your journal contained [illegible] of a meeting held at the Liverpool Medical Institution, and the subject under discussion was, "The Treatment of Intestinal Obstruction." During the discussion Mr. Banks is reported to have stated that the [illegible] treatment of this ailment for many years was opium, rest, and starvation. Being interested in this subject, I am desirous of knowing what authority Mr. Banks claims antiquity for this [illegible]

I am, Sir, yours obediently,

Birkenhead, Dec. 9th, 1884. ARTHUR [illegible]

"TRACHEOTOMY IN CROUP."

To the Editor of THE LANCET.

SIR,—An annotation in your issue of Dec. 6th under the above heading brings to notice a paper read by Dr. George W. Gay at the annual meeting of the American Surgical Society in May last. One extract is as follows: "It is a physical impossibility to suck anything out of the trachea unless air has a free ingress to supply the vacuum;" and against this want Dr. Gay recommends the forcible inflation of the lungs by means of blowing air through a catheter which had been passed down the trachea. If blood has escaped during the operation of tracheotomy down the windpipe, Dr. Gay states that this inflation is followed by the expulsion of a large quantity of blood.

May I ask, has the paper by Dr. Gay any number of cases in which he has practised the method? It would be interesting and very useful to have the minutest facts before us, and, if possible, not only the experience of Dr. Gay, but also of other American surgeons, especially those of Boston, amongst whom this practice of inflation seems in vogue.

This plan of inflation has never occurred to me as a means of removing foreign bodies, and my experience would not lead me to expect a hopeful result in an extreme case of blood obstruction, where the smaller bronchi must be filled with blood. I can, however, readily understand that with a catheter passed beyond an obstruction forcible inflation is a valuable means of procuring relief.

Let me instance the worst case of blood obstruction I have met with. A strong, well-made man, about twenty-five years of age, was ill with that erysipelatous, brawny condition of the neck known as "cervical cellulitis of Ludovici," which later on was complicated with œdema of the larynx. The night after the œdema had set in the man was seized with a very violent attack of dyspnœa, and it appeared, the nurse having left the room for a short time, that he fell off the sofa he was lying on, and was found on the floor, with his face "black," and breathing convulsively, with long distances between the respirations. Two neighbouring practitioners were immediately called in, and very shortly afterwards I arrived. Expecting that the man would be in the condition I have described, I had on going into the room a knife and tracheotomy tube ready in my hands. I found one of the medical gentlemen about to perform tracheotomy; but on my entering he asked me to operate, and as there was no time to be lost I cut into the trachea with one incision, and as quickly inserted the tube. It seemed that there were volumes of dark blood running down the windpipe, as well as pouring out externally, with no effort on the part of the patient to cough the blood up, or even the slightest attempt at any respiratory movement. He appeared, as he did when I entered the room, dead, and it was only the feeling that it was our duty to do all that could be done that made us think of trying to save the patient's life. To shorten the account: for about an hour we had to persevere in our efforts, my colleagues performing Silvester's method of respiration, whilst I at each expiratory movement sucked the blood through the tube; and when I had removed a good quantity, finding that there was no effort at natural inspiration, I occasionally, with an inspiratory phase, blew through the tube. The patient recovered fully, and was able in six weeks' time to return to his employment.

By this case it is proved that it is not "a physical impossibility to suck anything out of the trachea, unless air has a free ingress to supply the vacuum," and that forcible inflation would probably not always answer, but in this instance would have driven a large quantity of the blood, which must have been choking up the medium-sized bronchi, further into the lungs, and prevented its removal even by suction with the mouth. Doubtless inflation by the catheter would have a splendid effect in many instances of obstruction in the air-passages, and would do away with the inclination for the dangerous practice of using one's mouth to remove a tracheal obstruction.

I am, Sir, yours obediently,

Dec. 15th, 1884. A GENERAL PRACTITIONER.

COMMERCIAL ENTERPRISE.

To the Editor of THE LANCET.

SIR,—I enclose circulars which have recently reached me. They explain themselves, and are good specimens of a great nuisance and evil—a terrible evil if my wife either did or was inclined to tipple!

I am, Sir, yours truly,

Dec. 9th, 1884. CHIRURGUS.

"59, Mark-lane, and 1, Seething-lane, London, E.C.

"Dear Madam,—On hearing just now of the birth of your son, we tender our best wishes for his health and for your speedy recovery. If you would kindly allow us, we should have much pleasure in forwarding to you free per parcels post a sample bottle of our champagne, which, strongly recommended by medical men for convalescents, and especially for ladies, would, we trust, be agreeable to you, and induce you to favour us with your esteemed orders.—Yours obediently,

"Nov. 25th, 1884." "F. PIOT, DE FOREST, AND CO.

"59, Mark-lane, and 1, Seething-lane, London, E.C.

"Dear Madam,—In writing to you last week on the occasion of the birth of your son, who we hope is progressing favourably, as also yourself, we took the opportunity of offering you our champagne. We beg to apologise for having omitted to enclose you our price list (this probably having prevented you from asking for a sample). Our price for this special 'ladies' wine' is 36s. per doz. quart bottles, delivered, or 40s. per twenty-four half bottles; and in order to enable you to judge of the quality, we shall be glad to send you a sample free on receipt of your demand.—Yours obediently,

"Dec. 6th, 1884." "F. PIOT, DE FOREST, AND CO.

Paterfamilias.—There is not, we fear, any law to prevent the diffusion of such trash.

Enquirer.—Forcible introduction of the hand is not necessary. Dilatation by means of a tent will suffice.

Inquest and *M.D. Aberd.* have not enclosed their cards.

"MATERNAL IMPRESSIONS."

To the Editor of THE LANCET.

SIR,—As the following case is somewhat similar to that in your last issue under the above heading, I think it will prove of interest to your correspondent, and I shall be much obliged if you will be kind enough to insert it.

On the 5th inst. I attended Mrs. P—— in her eighth confinement, and delivered her of a male child, using instruments, as the case was somewhat complicated. Growing from the child's neck on the left side was a large tumour. All her previous children were free from any deformity, and there was no history of it in the family. The following is the account in her own words:—"In my second month of pregnancy I was standing at the front door, and saw a man pass who had a very large tumour hanging from his neck. On seeing it I felt a shudder go through me, but had not the slightest idea that it would affect my child, and never gave it one thought afterwards."

I have found that the tumour in the man whom the patient saw is also on the left side, and that there is no doubt about the facts of the case. I am, Sir, yours truly,

W. WATERFIELD, L.K.Q.C.P.I., L.R.C.S.

Stonehouse, Devon, Dec. 15th, 1884.

"UNSOUND MEAT."

To the Editor of THE LANCET.

SIR,—In connexion with the discussion on this subject I submit that the proper authority on the fitness of flesh for the food of man is the medical officer of health, and not the veterinary surgeon. The diagnosis of disease made by the latter, as an expert on the diseases of quadrupeds, should be accepted by the former as the basis on which to arrive at a conclusion, but nothing more. That a veterinary surgeon is no judge of what is proper food for human beings will to most minds be evident from the curious, but by no means rare, offer of the one at Tiverton, who, in support of his views, proposed lately to eat the questionable flesh—a line of argument only paralleled in absurdity by the proverbial backing of an opinion by a wager. Whatever ideas may be held with regard to the wholesomeness of flesh meat affected with the disease from which the animal in the Tiverton case was ailing, a disease on the nature of which veterinary surgeons hold contradictory ideas, some calling it a "fever" and others an "apoplexy," it will be admitted that no one would willingly eat such for food.

I am, Sir, yours truly,

Newcastle-upon-Tyne, Dec. 15th, 1884. HENRY E. ARMSTRONG.

REMARKABLE COLOURATION OF THE SKIN.

To the Editor of THE LANCET.

SIR,—As I believe the following to be a rare case, I should be glad if you would kindly insert it in THE LANCET.

A boy aged twelve was brought to me by his father in July last, suffering from psoriasis guttata. The patient was perfectly healthy in other respects. My treatment consisted of warm baths, with a quarter of a pound of carbonate of soda in each, every other evening, vaseline to be used locally by day, and an ointment of oxide of zinc, with seven minims of carbolic acid to the ounce, by night. After six weeks of this treatment (with five minim doses of liq. arsen. and five grains of pot. chlor. in a tablespoonful of water twice a day) I was surprised to find the patient's skin, from the neck to the knees and elbows, of a deep copper colour, which has remained so, the above treatment being still persevered with.

I should be happy to show the patient to any member of the profession interested in such cases, or to receive any suggestion as to treatment. I am, Sir, yours truly,

Dec. 8th, 1884. PHYSICIAN.

THE CASSAN FUND.

To the Editor of THE LANCET.

SIR,—Will you kindly acknowledge the donation of £1 1s. to this fund from Dr. Mackender, Gainsborough.

I am, Sir, yours faithfully,

H. F. LANCASTER.

ABSTRACTS OF

The "Brown" Lectures.

BY VICTOR HORSLEY, M.B., B.S., F.R.C.S.,
PROFESSOR-SUPERINTENDENT OF THE BROWN INSTITUTION.

LECTURES I. AND II.

THE THYROID GLAND; ITS RELATION TO THE PATHOLOGY OF MYXŒDEMA AND CRETINISM.

THE previous ignorance of the importance of the thyroid gland in the economy was only swept away by the attention aroused by Kocher and the two Reverdins. Mr. Horsley arranged the matter under consideration into five divisions. The first division treated of the anatomy and position of the thyroid gland. The bilobed form of the gland was held together by a capsule of connective tissue, which sent its trabeculæ into the substance dividing and supporting the gland tissue; the septa of connective tissue were the paths for the bloodvessels and lymphatics. The lymphatics have been proved by Baber, Boéchat, and Frey to assume the shape of large lacunæ at the very margin of the alveoli. The thyroid body imitates in its development a racemose gland, and was probably of a glandular nature. Virchow and Boéchat believe that the acini of the gland intercommunicate. Théophile de Bordeu believed that minute ducts brought about a communication between the thyroid and the trachea, and Ricou postulated the same idea of a duct-like communication between it and the larynx. The structures and relations, together with the histological phenomena attending the development, also supported the view that the thyroid was a gland. The glairy fluid of the acini is said by Kühne and Eichwald to contain mucin, though Gorup-Besanez saw a difference in its solubility in acetic acid. Baber's theory, to the effect that the mucinoid contents of the acini were secreted by the epithelium and reabsorbed by the lymphatics, was supported by the foregoing considerations. Simon seems to have been the author of the view formulated by Liebermeister and Guyon, which regarded the thyroid body as a regulator of the cerebral circulation. The view has also been held by Simon that the thyroid gland secretes a something necessary for the nutrition of the brain, but the changes in the central nervous system, after thyroidectomy, may be of a secondary nature. Luschka believed that the thyroid might act in a mechanical fashion, staving off the pressure of the contracting cervical muscles from the carotid arteries. The possible influence of the thyroid in hæmapoiesis was also referred to. Most of the foregoing views do not completely harmonise with what is known of the powers of the thyroid.

The effects of thyroidectomy were next considered. What happened if the thyroid were completely removed? Kocher showed that man becomes a cretin. Schiff, Wagner, Sanguirico, and Canalis removed the thyroid of dogs, and found that the animals became idiotic and died comatose. Mr. Horsley's experiments on the monkey showed that a condition, called by Mr. Ord myxœdema, arose when the thyroid was extirpated. The method of operating was next detailed. The post-mortem examination proved the limitation of the lesion to the gland. No ligatures were used. Perfect antiseptic precautions were carried out. The theory which ascribes the origin of myxœdema to the sympathetic system is inadequate in the light of the evidence afforded by Mr. Horsley's operations. Schiff's first set of experiments cannot be quoted, as no pains were taken to prevent septic poisoning. The symptoms following thyroidectomy in the monkey were tremors, (which came on in five days), pallor, leucocytosis, followed by oligœmia, paresis, puffiness about the eyelids, with swelling of the abdomen and increasing mental dulness. The temperature tends to become subnormal towards the end, which is usually ushered in by coma from five to seven weeks after the operation. The symptoms were next examined in detail. The nerve symptoms were the first to attract attention. Fibrillar twitchings of the muscles may be observed in the dog as the first symptoms, and Wagner states that the tremors are succeeded by clonic spasm, tetanus, and finally rigidity. In the monkey a slight fibrillar movement may be seen on the fifth day, first in the hands, next in the feet, and then in the jaws. These tremors merge into a constant tremor, which has resemblance to the ankle clonus. Paroxysms of muscular tremor and even convulsive movements have been observed, and tracings made, but tetanus was never seen in monkeys. With regard to the origin of the muscular movements, Schiff had found that they continued after section of the motor nerves, and Mr. Horsley after removing the cortical centres for the upper arm observed that they still remained. Voluntary movements diminished the tremors, but the inhalation of ether increased their activity, whilst reflex irritation stopped them altogether. The conclusion is that the movements are energised from the medulla oblongata or spinal cord. The rate of the tremors per second was the same as that in dogs (Lovèn), and is believed by Mr. Horsley to correspond with the tremors of paralysis agitans and allied conditions in man. Paresis of gradual onset, varying in intensity directly with the force of the tremors, and rigidity, always coexist. There is never complete paralysis, but wrist drop and the "paralytic posture" may be seen. Hemiplegia occasionally appeared, and then the tremors on the paralysed side disappeared, except from the jaws. Sensation may be a little blunted, and touch may be delayed when the tremors are in an advanced stage. The superficial reflexes were diminished; the knee-jerk was present, but never the ankle clonus. The centres of the lumbar region and medulla appeared to be unaffected. Slow hebetude ending in varying degrees of imbecility with easy disturbance of temper were the disorders related to the cortex of the brain. There was a steady fall in blood pressure and in the number of red discs for about fourteen days. Leucocytosis accompanied and kept pace with the oligæmia. The "buffy coat" was better marked, owing to the lessened tendency of the blood to coagulate. Mucin is not a normal constituent of blood, but was present after thyroidectomy, in quantities varying with the duration of life. There was an increase in the serum globulin, though other proteids remained normal in amount. The serum albumin was found by Dr. Halliburton not to be separable into three forms. The sudden appearance and disappearance of dyspnœa were interpreted by Mr. Horsley to be of bulbar origin, owing to the absence of other physical signs. The recurrent larngeal nerves were always found to be healthy, and the larynx was normal in every way. The hypertrophy of the salivary glands was a novel feature, and due to extreme production of mucin, whilst, strange to say, the parotid comes to secrete mucin. The appetite fails immediately after the operation, but soon revives, only however to become ravenous prior to its final failure just before death. Credé, Zesas, and others have observed a connexion between the spleen and the thyroid, and Mr. Horsley has detected an increase in the splenic dulness during life, which was found after death to be due to general enlargement of the spleen. Distension of the intestines with hypertrophy of the omentum were the chief factors of the abdominal swelling. The small amount of peritoneal fluid contained mucin. The urine was normal in quality, and with the exception of occasional transient glycosuria and a normal quantity of mucin, nothing remains to be said on this score. The genitalia were normal. The marked pallor of the skin, which was apparently of normal humidity, the swelling of the face and eyelids, and the atrophy of the hair were dilated upon. It was curious to observe the atrophy and greyness of the hair about the buttocks, and one was reminded of the bedsores of man. The temperature curves show after operation a slight rise, followed by a fall to the normal. The morning fall and evening rise are exaggerated when the tremors set in. In monkeys Mr. Horsley does not find a high fever when the tremors are on, in this respect differing from what Schiff has described in the dog. The temperature slowly falls after the tremors have reached their height until a subnormal heat of body is registered prior to death, which is ushered in by cold surface and extremities, though shivering was never seen. The constant and small perversions of nutrition give rise to a clinical picture which has its counterpart in the myxœdema of man. At the post-mortem examination of the monkeys the subcutaneous tissues are found to be notably altered, being swollen, jelly-like, bright shining, and excessively sticky. The increase of the altered connective tissue is most marked in the triangles of the neck and over the hypochrondria. The same condition is observed in the tissues of the mediastinum and omentum, as well as along the coronary arteries and the auriculo-ventricular groove. Atrophic changes could be seen when the fatty tissue

Digitized by Google

which remained was examined microscopically; these appearances were typically seen in the fat about the auriculo-ventricular grooves. No changes were seen in the bursa, but congestion of the synovial membranes was present without effusion. The bones and cartilages showed no positive alterations. An increase was observed in the connective tissue of the muscles. The connective tissue of the whole body may be said to be increased with a mucoid degeneration of the ground substance and atrophy of fat. The enlargement of the salivary glands has been noticed, and chemical analysis showed that the parotid of the monkeys in question contained as much as 1·21 per 1000 of mucin. The proportion of mucin in the submaxillary gland was increased from ·01 to 4·6 per 1000. There is swelling of the mucous membrane of the alimentary canal, and much slime in the motions. The brain and spinal cord were pale and somewhat wasted, and the meshes of the pia mater were distended with fluid. No sign of disease was detected in the musculo-spiral nerve or in the sympathetic system. The other nervous tissues have not yet been completely examined.

The various theories advanced as to the nature of cretinism and goitre were next passed in review. Myxœdema, cachexia strumipriva, and cretinism were outlined from the accounts given respectively by Ord, Kocher, and Hilton Fagge, and the conclusion that all these processes were of identical nature was arrived at. These morbid processes are most probably dependent upon profound changes set up by injury to or ablation (actual or virtual) of the thyroid body. Kocher's view that a chronic asphyxia led to the cachexia strumipriva as a result of the atrophy and softening of the trachea was not accepted by Mr. Horsley, on the ground that the trachea and gullet may remain healthy, and that chronic stenosis of the trachea is not followed by "myxœdema." Dr. Hadden's theory of capillary spasm does not hold good, because the sympathetics were found to be healthy, and because Schiff's experiments on irritation of the sympathetic nerves did not give rise to "myxœdema." The increase of connective-tissue must be regarded as an epiphenomenon of the changes found in myxœdema.

Mr. Horsley next draws up a tabular statement of certain facts which may be found a useful aid in further investigation:—

1. The thyroid gland appears to consist of two distinct portions: (*a*) glandular, having the function of excreting mucin (?); (*b*) highly vascular lymphoid nodules, having a (?) hæmatogenous function.

2. Excision of the gland is followed by an increase in the amount of mucin in the tissues, an increase in the activity of the muciparous glands, and the assumption of a muciparous function by glands which usually yield no mucin.

3. Excision of the glands is followed by the profound changes in the blood already indicated.

4. Excision of the gland is followed by nerve symptoms, indicating changes in the lowest motor centres, which cause tremors, with rigidity and paresis, as well as alterations in the higher cortical centres with the production of imbecility, and ultimately death in the comatose state.

Having thus summarised the changes, Mr. Horsley states his belief that myxœdema and its allies are due to the loss of the thyroid body—a virtual, if not an actual, loss. No doubt vaso-motor or trophic lesions may be the immediate cause of the changes, but even then the functional or actual want of a thyroid body would be the parent cause of the trophic or vaso-motor disorder. The view that the thyroid gland is an excretory organ received strong support from the experimental facts. The removal of one lobe of the thyroid causes enlargement of the other, and the subsequent removal of the second lobe is followed by myxœdema. May it not therefore be that the thyroid excretes a mucinoid material which is harmful to the organism, and that the loss of this excreting function entails death?

The surgical treatment of the thyroid gland was next discussed. The conditions calling for treatment are hypertrophy or adenoma, with or without some amount of cystic degeneration or fibroid overgrowth, cystic disease, malignant new growths. Removal was the only method for the last condition. The partial or total removal of the tumour is said to have cured one case of exophthalmic goitre, and partial excision is perhaps the only treatment which holds out a possibility of cure. Simple goitre may be treated by injection or removal. Injection may be simple or combined with laceration by a needle, as practised by Billroth. Sudden death has followed simple injection; and Billroth's method may be followed by serious inflammation. Before injecting it would be well to adopt Demme's plan of waiting to see whether a vein has been wounded or not. Mr. Horsley believes that the sudden death is due to thrombosis, the result of the entrance of iodine and not air into the circulation. The total removal of the thyroid is condemned, as good results may be obtained by removal of a portion. Mr. Sydney Jones's operation of excision of the isthmus between silk ligatures has been most successful.

LECTURE III.

TRAUMATIC FEVER.

The expression "traumatic fever" has universally been employed to denote the febrile state which usually follows an injury to the body with or without a lesion of the skin or mucous membranes. The term at present embraced fevers of widely different natures, as Lucas Championnière proved by describing puerperal fever, pyæmic fever that of septicæmia, and urethral fever under the same title. Erichsen separates septic, traumatic, and urethral fevers. Mr. Horsley limits the term traumatic fever to fever following a simple injury and uncomplicated by septic or other possible sources of pyrexia. A simple injury would imply one in which there was a solution of continuity of any tissue without exposure to the environment. A classification of fevers following injuries gave: (1) traumatic fever, (2) aseptic fever, (3) septic fever, (4) neurotic fever. The second fever is that which accompanies a wound treated perfectly antiseptically; Volkmann believes that a pyrogen is developed at the site of an injury, and then absorbed. But it must be remembered that a fracture and an amputation wound differ in this respect, that the latter has chemical substances brought directly in contact with it, and although carbolic acid is said to lower the temperature, yet it must be confessed that its presence adds a new element for consideration. Taking 168 cases of simple fracture, Mr. Horsley finds that about 92 per cent. were marked by febrile reaction. Volkmann and another, who only examined eleven cases, found the per centage to be 78·5, while Augerer gives the proportion as 70 per cent.; ten cases only were investigated. Stickler found that twelve out of thirteen had fever, which gives a percentage of 92. Chauffard believes that racial characteristics would explain the differences. Two groups of cases are separable in Mr. Horsley's cases; the first group being characterised by rapid rise of temperature and little or no swelling, the second group being attended with swelling and a slow rise of temperature.

In the first group attention to a composite chart constructed from sixty cases showed in one variety a rapid rise in an hour to a high point, and the rise attained gradually to a higher level during the next twenty hours, thence onwards there was a gradual fall to the normal in about 160 hours, or nearly a week. Another variety of the same kind of pyrexia was observed where the rise in temperature was slower by a few hours, and lasted only about three days and a half. The first or severer variety generally occurred in individuals below the age of thirty. In the second variety the large number of cases were above the age of thirty-five. In the differences between these two types of the first group we may see another instance of the diminished activity of the metabolism of the tissues in more advanced ages. In the type of the second group a rapid rise nearly to 100° is observed; then the curve steadily rises for two days, with slight remissions, to 101°. From this point it falls more rapidly until it reaches 99° at about the eightieth hour; and though this fall to the normal always occurs, yet it is soon followed by a second rise to above 100°, but seldom reaching 101°. This second rise is peculiar, constant, and almost invariably occurs at the 112th hour. From this second acme the temperature falls in two or three days to the normal. The total duration of this third type of fever averages seven days and a half, but very frequently it is prolonged to the tenth or twelfth day. The statistics showed that this type occurs most frequently in the young and old, whilst the middle aged escape; the majority occurred below the age of thirty-five. The presence of greater swelling in these cases indicates, *cæteris paribus*, a great amount of damage, and tissues are more likely to be damaged in those individuals whose age approaches either extreme of life. Was there any explanation for the absence of febrile reaction in the 9 per cent? The average age of those who had no fever

Digitized by Google

was forty. In half the cases there was sufficient swelling to call for special attention. The femur and tibia were each fractured three times; the fibula once, and both bones of the leg five times. Of the twelve patients nearly all appeared to have enjoyed good health. In the group of cases which includes the first two types of fever the sharp ends of the fragments of the broken bones irritated the torn branches of nerve and ruptured muscle. And there is more or less extravasated blood, and the idea of more or less absorption of fat from the damaged marrow must be entertained. So that there are three possible exciting causes of a rise of temperature:—(1) Moderate stimulation of an afferent nerve; (2) absorption of extravasated blood; (3) so-called fat embolism. Severe stimulation of afferent nerves causes depression of temperature, whereas gentle stimulation causes a rise of temperature in the part supplied by the nerve. The possibility of heat centres in the spinal cord and elsewhere, which can be influenced in a reflex manner, was spoken of as affording an explanation.

Angerer has shown that the artificial production of a hæmatoma is followed by marked fever within four hours. Albert and Stricker have observed a rise of 1° C. in a dog as the result of the exposure of a vessel with a view of injecting into it. Absorption and nerve actions may have played parts in these cases. A rapid rise followed by a gradual fall is probably due to anything but the absorption of a pyrogenic substance. Mr. Horsley could adduce nothing to support the theory of fat embolism as a cause of the fever. In the surgical condition known as "tension" the possibility of a centripetal stimulation causing fever was great. Idiosyncrasy, too, received its best explanation on the neurotic view of the first two types of traumatic fever.

The peculiar type of fever of the second group of cases was ascribed to the development and progress of the œdema, or swelling. Angerer injected under the skin of the forearm of Fehleisen sufficient defibrinated ox blood to cause a tumour of the size of an apple; this gradually disappeared in a few hours, and was succeeded by a secondary swelling of the arm, together with severe constitutional symptoms of fever. The temperature chart of this case was identical with that of Mr. Horsley's third type, and the pathology of both was probably the same. Tension or absorption might be at work in the production of part of the febrile course. The occurrence of œdema is very comprehensible when the damage to the walls of the bloodvessels, with the thrombosis of some vessels and extravasation of blood from others, is borne in mind.

LECTURE IV.

ON URETHRAL FEVER.

In the fever known as urethral fever it would appear that we have a more probable example of the influence of the nervous system. In what Mr. Horsley calls the "fulminating" form of urethral fever the rise of temperature occurs immediately upon the operation, and the possibility of a septic influence is regarded as extremely small and improbable. Confirmatory evidence is afforded in the fact that the most rapid and severe form of urethral fever may follow the passage of a blunt instrument without any wounding of the mucous membrane. The fulminating form of urethral fever occurs in 63 per cent. of the cases by catheterism; the mild subacute form is caused by internal urethrotomy in 76 per cent. of the cases. The two forms of urethral fever already mentioned are absolutely distinct from uræmic fever or any kind of fever which may accompany renal disease. In the fulminating form the temperature shoots up to its highest point (above 104°), on the average in four hours and a half. In the next two hours it falls nearly half way back again, and then the normal is gained gradually by the end of twenty hours. The average age of the patient is forty-two. The symptoms of stricture are almost invariably of recent date, the average duration being eighteen months.

Sir Wm. Ferguson had observed that the greatest constitutional disturbance occurred in those cases which had not undergone previous treatment. Mr. Horsley states that 40 per cent. of the fulminating variety had not been treated at all; 40 per cent. had been unsuccessfully catheterised, and the remainder had been treated only a short time for urgent retention of urine. In the second variety the pyrexia rises at a rate at least five times as slow as the first form; the rise is frequently preceded by a fall due to shock. The temperature as indicated by the diagram is seen to fall 1° in three hours, and then to occupy nearly double that time in regaining the normal, from which point it rises slowly at first, but afterwards more rapidly towards the highest point, which is usually reached about the twenty-third hour. The small preliminary rise at about the eleventh hour is very constant, and is possibly the ordinary evening rise postponed by the influence of the shock due to the operation which was almost invariably performed about 2 P.M. Age would appear to have but little to say in the etiology of this variety; as a matter of fact the average age was lower than that of the first form—namely, thirty-eight compared with forty-two.

We should not expect to find that the difference between the two forms is in any way dependent upon age. The age of the stricture, however, probably has a great deal to do with the etiology of the subacute variety which usually follows operation on an old stricture, the average age of the stricture being eight years. The less degree of fever is probably dependent also upon the nature of the operation, which was internal urethrotomy in 76 per cent. of the cases. The characteristic rigor with which we are so familiar after operation on the urethra most commonly occurs just before the acme of the fever is reached, whether we consider the fulminating or subacute variety. The duration of the rigor has been observed to be proportionate with the intensity of the pyrexial disturbance. Sir Joseph Fayrer and others have remarked upon the influence of malaria in the causation of urethral fever. Cases in which no fever followed the operation appear to find their explanation in the long duration of the stricture (nine years and a half on the average), and in the nature of the operation, which was continuous dilatation and internal urethrotomy in about two-thirds of the cases. Cases of external urethrotomy and perineal section, being frequently complicated with other conditions, are best left out of consideration. To sum up, we may say that the most severe urethral pyrexia follows catheterism most commonly, and occurs in persons of middle age suffering from very recently developed strictures; while the less severe form occurs, as a rule, after internal urethrotomy in strictures of very long standing, and which have been freely treated. Finally, the apyretic state is commoner in still older strictures and after either internal urethrotomy or continuous dilatation with catheters.

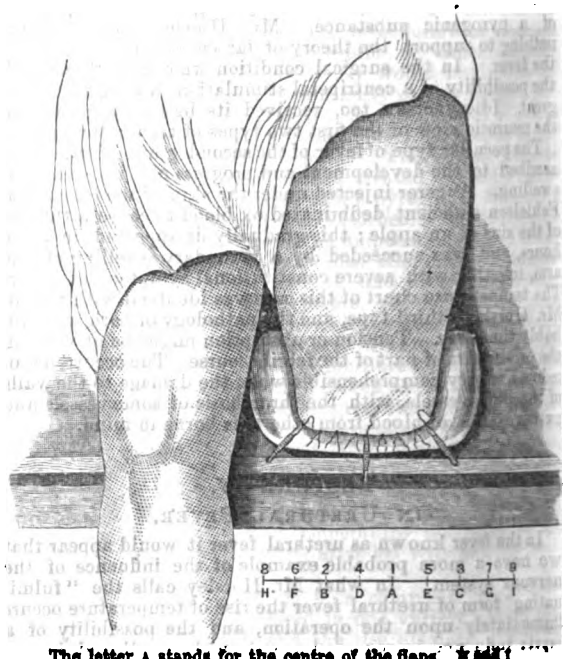
Dealing next with the pathology, Mr. Horsley draws attention to the anatomical and physiological conditions involved in the question. The existence of centres all along the spinal cord which are concerned with the formation of heat has been rendered most probable from the experimental researches of Naunyn, Quincke, Wood, and Heidenhain, as well as by clinical observations, and the paper by Hale White is mentioned in this regard. Whether the spinal centres are of a thermo-genetic or thermo-inhibitory nature still remains doubtful, though the latter view is most probable. The spinal centres are governed by supreme centres situate in the cortex cerebri. These centres may be influenced by reflex irritation, and Mr. Horsley is of opinion that urethral fever owns a neurotic cause. Septic inoculation or absorption of blood are clearly incompetent to explain the severe fever which follows catheterisation with a blunt instrument where no blood is drawn. This belief is strengthened by the fact that the rise of temperature in the case of absorption does not take place till twenty-four to forty-eight hours have elapsed, whereas the curve of severe urethal fever reaches its height within four hours. Moreover, the fulminating form occurs in association with the first treatment of recent strictures, when the nerves about the stricture are, so to speak, in an abnormally excited state. Previous treatment, too, would tend to lessen the force of each succeeding interference, and so anything like a severe stimulation of the nerve fibres would be avoided. The safest and most fever-free operations are continuous and very gradual dilatations and internal urethrotomy. Roser has shown, in opposition to Sédillot's view of septic absorption, that in other simple operations, such as amputation of the penis and lithotomy, typical urethral fever is never seen. Surely this immunity is due to the freedom of the incision and consequent absence of traction upon the nerves in the mucous membrane. In internal urethrotomy we have a close parallel, complicated, however, by the wedge-like action which inflicts a stretching in addition to the incision. With regard to the influence of the administration of ether, and to the fact that Mr. Holt had performed this operation 670 times with but two deaths, the following considerations are urged. Dr. G. Johnson long ago showed that chloroform tended to suppress rigors, and it has been proved that ether,

Digitized by Google

alcohol, morphia, quinine, and other alkaloids tend to prevent the development of pyrexia and its accompaniments. These facts favour the neurotic theory of fever, as does also the circumstance that no matter what the source of the fever the alkaloids mentioned still exert their controlling force. When Mr. Holt did not use an anæsthetic the occurrence of urethral fever was by no means uncommon. The large size of the stricture and the plan of preparing patients by the use of quinine and opium may account for the absence of fever and for the low mortality of his operations in Mr. Holt's hands. Malherbe gives it as his opinion that internal urethrotomy is as "pyrogenous" as divulsion or rupture of the stricture, but Mr. Horsley's statistics do not support this idea. Having referred to Mr. Marcus Beck's observations, Mr. Horsley passes on to give certain conclusions at which he arrived as the result of observations on the quantity and quality of the urine in five cases of internal urethrotomy. As a rule the amount of urine excreted is diminished for one week following the operation. In the one case which had no fever, the amount of urine was greatly increased for ten days after the operation. The less degree of hyperæmia may possibly explain this augmentation. The discharge of nitrogen is variable for the first few days after the operation, but it soon becomes normal, and then slightly increases. Urethral fever is a reflex symptom, just as much as renal congestion and altered excretion are.

In respect of treatment, the patient should be prepared by being kept in bed, put under the influence of quinine, previously catheterised gradually up to No. 4 E., given one-third of a grain of morphia an hour before the operation, and operated upon under the influence of ether, or, better, chloroform. The operation should be internal urethrotomy. No instrument should be left in, and none should be passed for four days. Diffusible stimulant and external heat should be aided by the employment of chloroform or morphia if a rigor set in.

Remarks
ON THE
GENERAL PERFORMANCE AND TREATMENT OF AMPUTATIONS.



By JAS. WHITSON, M.D., F.F.P.S.G., F.R.M.S.,
ASSISTANT-SURGEON, GLASGOW ROYAL INFIRMARY.

(*Concluded from p. 1082.*)

Suturing of the Flaps.

IN all operative procedure it is desirable to leave a small scar, and with this end in view the suturing of the flaps ought to be carefully attended to. An accurate but easy apposition of their edges is necessary for successful union, and the first requisite for securing this is abundance of skin.[1] If too much pressure comes to be exercised on the stitches their division becomes imperative, even at the expense of additional cicatricial tissue, because the proximity of the margins under these circumstances is no longer desirable, and unless promptly freed will result in tension.[2] It is fortunate for the patient, however, that sutures when unfairly taxed have a tendency to cut their way outwards. Before passing the stitches a pair of stout artery forceps may be placed in the centre as well as at either angle of the flaps (Fig. 1). This manœuvre greatly facilitates the apposition of the margins, and sutures may then be inserted at the points A, B, and C. Two ought to follow at D and E, the spaces being regularly divided in this way till the whole line is completed. If cellular tissue be allowed to protrude an indelible cicatrix is the result, but this may be almost entirely avoided by stretching the edges one upon the other during the process. If, for example, we are about to insert stitch 2 (Fig. 1) an assistant will aid matters considerably by extending from the points A and H. If No. 7 requires to be dealt with, the points C and I may be selected for a similar purpose, and so on. By thus proceeding on a uniform system the sutures are unlikely to drag, and under proper after-treatment the wound heals with a very trifling cicatrix. When the sutures are passed continuously from one side to the other, a pouch almost invariably remains at the end, and mars the line of union. A needle-holder[3] is serviceable in the introduction of the sutures; and when the skin is tough, as in Syme's amputation at the ankle-joint, it is an invaluable auxiliary. Curved needles are the most convenient to work with, and to be preferred to the straight variety. Chromicised catgut when properly prepared[4] is the most convenient suture to work with. It is easy of manipulation, and the pliancy which it possesses permits of a nice degree of relationship being established between the edges of wounds. Under favourable circumstances its presence occasions no uneasiness, and we are never compelled, as in the case of wire, to take down the dressings in order to remove it, because that part of the thread which is in contact with the tissues becomes absorbed. In this way the upper portion is set free, and will at the end of a certain time be found lying loose on the surface of the skin. Stitches of silver wire are not secured with the same facility as those of gut,

FIG. 1.

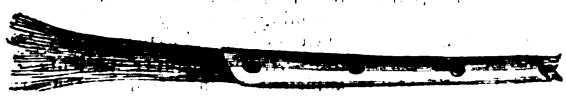
The letter A stands for the centre of the flaps. H and I represent their outer and inner corners, while B and C indicate points respectively equidistant from H and A, and from I and A. The order followed in the insertion of the sutures is indicated by the numerals.

while the stiffness and general want of adaptability peculiar to metallic sutures render their ends liable to catch in the dressings and make the extraction painful to the patient. *Cæteris paribus*, sutures of a definite thickness maintain their hold best; but the stronger the thread of wire which is used the more intractable does it become, and the less capability does it press on the structures within its grasp; this latter cannot be attributed to catgut, inasmuch as its pliancy continues the same in all its sizes, and an equable compression is exercised by it throughout its entire circumference. Pus

[1] Should the element of covering happen to be deficient in a stump, button sutures will to some extent relieve the strain on the surrounding parts.

[2] Any tendency towards inflammation will be speedily revealed by the thermometer, and if the temperature is observed to rise much beyond the normal the stump had better be examined. If tension exists it should be relieved at once.

[3] The needle-holder manufactured by Lüer of Vienna is a excellent instrument, simple in its construction, and easily worked. Dieffenbach's needle-holder, as described by Billroth (Surgical Pathology, page 61), is also to be recommended.



[4] A good deal of the material which is sold under the name of "chromicised catgut" is defective in one of two ways. If insufficiently chromicised, it yields to the action of the tissues in forty-eight or seventy-two hours; and on the other hand, if hardened overmuch it is wanting in pliancy. By Macewen's method of preparation catgut is allowed to steep from four to seven days in the chromic acid mixture, the length of time during which it is retained there being determined by the degree of resistance it is thought desirable to impart. When taken out of this solution the gut should be washed in water, and dried before being immersed in phenol and glycerine (1 to 40) in which to remain somewhat hard.

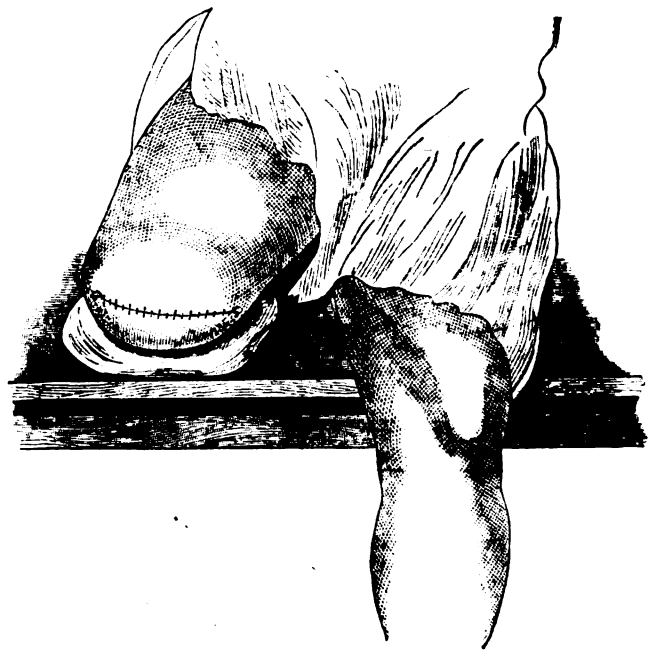
W. H. Pancoast of Philadelphia advocates an iron-dyed silk which he has been in the habit of using for some time.[5]

Drainage.

Drainage is now recognised as an important factor in the treatment of amputations, for if discharge does not obtain egress unpleasant consequences speedily manifest themselves and retard the progress of reparative action. A good deal of effusion succeeds the removal of a limb, and many surgeons obviate its accumulation by leaving the sides of the flaps partially open for the first forty-eight or seventy-two hours. This method certainly effects its purpose, but it should be borne in mind that the edges of wounds have begun to granulate by the end of that time, and it is therefore clear that their roughened surfaces cannot afterwards be approximated with the precision of freshly cut tissue, nor can the parts accommodate themselves so readily to each other after being kept apart for some days. The scar which follows such a mode of procedure is larger than it otherwise would be, and in addition to being unsightly may prove a source of future inconvenience. The first step towards improvement in this direction was the introduction by Chassaignac of indiarubber tubes of various sizes, which are perforated at regular intervals in order to increase their action. If favourably placed these agents make excellent drains, but owing to the pliability of caoutchouc their channel is liable to become deflected or compressed, and the conducting power which would otherwise be possessed by them may thus come to be interfered with. The decalcified chicken bone drainage tubes of Macewen (see Fig. 2) fulfil the design of their inventor admirably, and in fresh wounds are to be preferred to those previously mentioned. They are threaded with horsehair, which maintains their calibre, and at the same time prevents occlusion of their channels by blood-clot. If care be taken to leave the ends of sufficient length, a syphon action is induced, the result of which is that the discharge is led into the dressings and the stump kept dry and

FIG. 2.

Decalcified drainage-tube of Macewen.



comfortable. It is usual to withdraw the hair at the expiration of forty-eight hours, because the sero-sanguineous exudation following an amputation has in the majority of aseptic cases then ceased. The tubes in question are easily prepared, and when placed in contact with tissues whose vitality has not been lowered are, as a rule, ultimately absorbed. Hair has, however, one disadvantage. It will not drain pus, and when suppuration is going on the indiarubber tubes of Chassaignac should be used.

Catgut[6] is inferior to hair as a conductor of fluid, owing to its lacking the straightness and hardness of capillary fibre. Its flexibility also renders it prone to displacement. Threads of gut have the additional drawback of being somewhat irregular in their cylinder, and do not on this account lie so well together as the rounded filaments of hair. Fewer can thus be inserted in a given space, and their united action must therefore be less, for numerical superiority—other things being on a par—increases power in a definite ratio as we ascend the scale.

We have now to consider the question of allocation, and decide whether it will be best to confine the drainage-tubes to any one position or distribute them regularly throughout the stump. In agriculture it has long been recognised as an axiom that if land is to be brought to the highest state of perfection it must be deprived of superfluous moisture. To effect this the skilful farmer does not construct one or two large drains in the central or lateral portions of his fields, but cuts instead a regular series of minor channels, taking care to utilise any slope in the ground and to see to the subsequent disposition of what has been abstracted from the soil.[7] The same principles hold good in surgery, and with a view to the better solution of this problem we may now ask ourselves the question, What is the area of discharge? The major proportion of the exudation immediately succeeding an amputation takes its origin in the muscular tissues enveloping a limb, because there are many small vessels divided here which are too minute to tie, and whose mouths in consequence will remain relaxed for some time. As blood, in common with other liquid bodies, obeys the ordinary laws of gravity by seeking its lowest level, we may thus safely proceed upon the assumption that several dependent exits will most favour its escape.

The practice of introducing indiarubber tubes at either corner of the flaps may aid matters provided the position occupied by them is favourable to drainage, but it should be remembered that if the posterior flap is of any length the bulk of the discharge will be compelled to travel some distance before it can pass out. Should the under flap remain unsupported and thus fall away from the upper, the proximal ends of the tubes are certain to be tilted downwards, owing to the fact that their distal extremities from being generally fastened by stitches are necessarily pointing upwards, and are almost useless for conducting purposes from the fact that fluid material cannot ascend. Hence it follows, if the edges of the flaps have been accurately sutured, that the bulk of the discharge is retained within, and the overflow alone is able to well away.[8] (See Fig. 3.) The same thing is also

FIG. 3.

liable to happen when a tube is passed from one side to the other. An excellent method of drainage, which effectually removes the difficulties referred to, is that of piercing the posterior flap[9] at different points, and inserting drainage-tubes into the openings so made. Discharge thus finds a ready exit, and its early liberation materially contributes towards the maintaining of the wounded surfaces in a condition favourable to the advance of repair. (See Fig. 4.)

Dressing of the Stump.

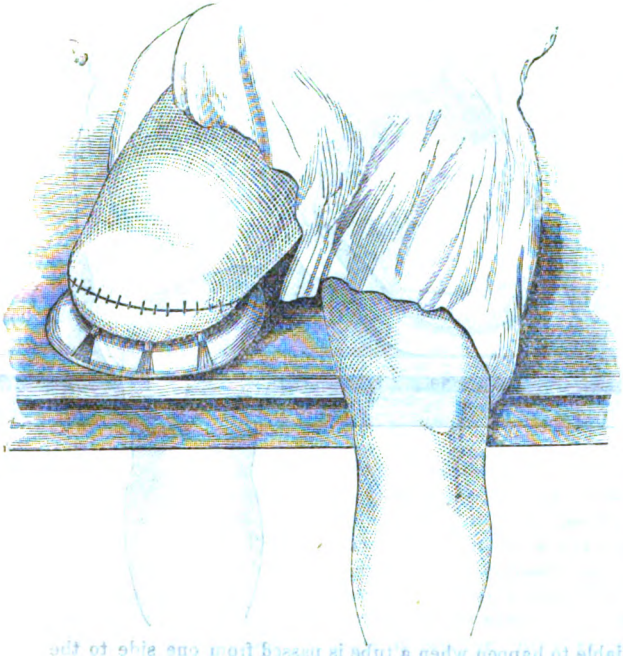
After arranging the drainage-tubes and fastening the sutures,[10] we require to dress the stump. Formerly strips of lint soaked in camphorated or other oil, and retained in position by means of calico bandages, were almost universally employed for this purpose. Lint when soaked with blood becomes hard, and a want of resiliency in a dressing soon proves irksome to the patient, while its frequent removal disturbs the process of healing, and is inconvenient

[5] For further particulars on this subject, see an article on Iron-Dyed Silk in the Philadelphia Medical Bulletin, August, 1883.

[6] Catgut, when used as a drain, should be chromicised; if not, it gives way too soon.

[7] The injurious influence which stagnant water exercises in its immediate neighbourhood is too well known to need further comment.

[8] We see the same thing happening in the case of a distended bladder.



[9] A pair of dressing forceps answers very well for this purpose, and the exit can easily be enlarged by opening the handles of the instrument. When this method is carried out, the tubes are best inserted before the suturing of the flaps. In every case where I have seen decalcified drainage-tubes used, the blood began to drop from them at once, and continued doing so while they were under observation.

[10] Great care should be taken to see that the stitches do not drag.

Digitized by Google

otherwise. Neither does it permit of sanguineous or purulent material passing readily through it, and its capacity in this direction will be still further lessened when impregnated with an oleaginous compound. Should the amount of discharge happen to be profuse, much of it on this account must be pent-up within the wound—a state of matters which ought to be carefully guarded against. After an extended trial of different materials Mr. Lister ultimately (1871) adopted gauze as the most suitable dressing for wounded surfaces, and the fact that this article continues to be so employed is the best evidence in favour of its superiority that could be adduced. Its numerous layers afford complete protection from external influences, porosity of fibre confers great absorbent power, and perfect asepticity permits of its being retained in position for some time—essential requisites for the progress of healthy action. Carbolised tow is a valuable adjunct to gauze.[11] After the first few strips of the latter have been applied several well-teased rolls of the former when investing the limb will be found to yield a firm as well as elastic support and assist in taking up discharge. It is usual, when following the antiseptic method of treatment, to dress an amputation forty-eight hours after its performance, provided there is no previous evidence of stain. If decalcified drainage-tubes have been called into requisition, the hair with which these agents have been

FIG. 4.

threaded may then be withdrawn. It occasionally happens that at the expiration of this period a quantity of clotted blood has accumulated within the stump. In such cases a stitch or two should be cut and the mass cleared away. If the cavity be washed out, it is advisable to do so gently,[12] and with a tepid solution of carbolic acid (1 to 40). Rough measures do harm, and fluid injected forcibly into a recent wound stimulates the tissues to increased secretion, and thus continues, rather than mitigates, the evil. If sufficient attention has been paid to details, the second dressing should not require removal for a week or even longer. In doing so an assistant should be instructed to pass both his hands under the limb and press the flaps forward, so that no strain may be placed upon them. A splint of Gooch padded with tow and with the corners rounded off may be advantageously applied to the limb; it renders the parts less susceptible to movement, and thus promotes the general weal. If the discharge happens to be profuse, stains speedily make themselves apparent at the lowest end of the dressings. Should it be inconvenient to remove this when these are first observed, a few folds of gauze may be secured round the parts till the whole can be replaced. Under favourable circumstances cicatrisation may be expected in the course of four or five weeks.

[11] Iodoform may be sprinkled over gauze with advantage, more particularly if it be intended to keep the dressing on for some time.

[12] A syphon is the best instrument for this purpose; the flow of water which it gives is uniform and steady, whereas in syringes it is apt to be jerky and uncertain.

LUNACY LAW REFORM.

BY ERNEST W. WHITE, M.B. LOND., M.R.C.P.

As reform in connexion with the heterogeneous legal enactments known as the lunacy laws is imminent, it behoves all who have had any experience in their operation to bring to notice the defects of the existing system, and to suggest remedies for these defects. With this end in view, I propose to discuss the subject from a medico-legal standpoint, and, for the sake of brevity, shall adopt the following headings:—I. Order of Admission. II. Medical Certificates. III. Care and Treatment. IV. Discharge on Recovery or otherwise.

I. *Order of Admission.—A.* For pauper patients an order of admission to the superintendent of the county or borough asylum (16 & 17 Vict., c. 97, s. 67 and Schedule F, No. 1) is necessary. This is usually made by a justice of the peace, but may on emergency (when the patient on account of health or other cause is unable to go before a magistrate) be signed by an officiating clergyman and relieving officer (or overseer). Protection is certainly needed against the abuse of this latter clause, orders being frequently signed by the chaplain of a union and the relieving officer to avoid the trouble of getting the signature of a justice of the peace. *B.* For private patients not found lunatic by inquisition the law is different; the so-called order, which is virtually a request to the proprietor or superintendent (16 & 17 Vict., c. 96, s. 4, and Schedule A, No. 1), is made by a relative or friend. This mode of procedure stands condemned by public opinion, and the most practicable remedy appears to be that the order or request of the relative or friend should be countersigned, before becoming valid, by a justice of the peace, on the recommendation of a local expert.

II. *Medical Certificates.—A.* For pauper patients one medical certificate is sufficient in addition to the order (16 & 17 Vict., c. 97, s. 67, and Schedule F, No. 3). This certificate is made by the medical officer of the union, who is, as a rule, conversant with the case. But there are patients who rank in the county and borough asylums as paupers whose friends pay to the union authorities the entire amount of their maintenance cost. These persons are sent to the public asylums because their relatives are unable to meet the extra expense attending treatment in a private institution. Now, the mode of certification in these cases is by no means satisfactory. The patient has probably been for some weeks under private medical treatment; the medical man in attendance and the relatives feel they cannot undertake the responsibility any longer. The patient is presumably insane. The relieving officer is applied to; he brings the case under the notice of a magistrate; an order is made to the district medical officer of the union to examine and certify. Now, it very frequently happens that this district medical officer has never previously attended the patient, and is quite unacquainted with the family history. Yet, I presume, it is one of the perquisites of his office to be called in to certify; so, in sublime ignorance of the previous history, he makes his examination and signs the certificate. Moreover, it not unfrequently happens that a patient of this class is taken to the union and remains there for several days to await examination, an unnecessary humiliation for the patient and the relatives. *B.* For private patients (16 & 17 Vict., c. 96, s. 4, and Schedule A, No. 2, and 25 & 26 Vict., c. 111, s. 47) two medical certificates are demanded in addition to the order, except on emergency, when one certificate remains valid for three days, at the expiration of which time two other certificates must be obtained. Now, while the law is very exact with regard to the "disqualifications" of medical men by reason of relationship, professional connexion, or interest in the asylum chosen for reception, and moreover requires that the medical examination in each case shall be separate and distinct, it makes no mention of the "qualifications" deemed necessary in the medical certifiers, beyond the fact that they must be "duly registered medical practitioners." The defects here are evident: 1. There is no com-

Digitized by Google

pulsory education of medical students in mental diseases, and the class of psychological medicine is very scantily attended; I might even say it is virtually non-existent at many of the schools. 2. The qualifying examinations demand no knowledge of mental diseases. 3. Nine out of ten medical men have never seen a case of insanity until they are called upon in practice to examine a supposed lunatic and certify if necessary. What, then, I would ask, is the value of such a "skilled" certificate? And yet by virtue of an order signed by a relative or friend and two such certificates the subject can be deprived of his freedom! It being illegal for medical men to act in consultation on the case is certainly also a mistake, and opposed to the golden rule that "two heads are better than one." The origin of this separate examination clause was a desire to prevent collusion. In favour of the adequacy of the present system of certification, it has been stated that the medical officer of an asylum rarely returns a patient thus admitted as "not insane;" but, I would add, most medical officers are ready to admit that cases not unfrequently occur which have been unnecessarily sent to the asylum. The possible remedies for these defects are as follows:—1. The appointment of district experts as medical officers of insanity, occupying analogous posts with that of coroner or medical officer of health, with fixed salaries; these officers to be elected from their experience in the specialty, and to be allowed to practise as pure physicians. Their duties would be to examine all supposed lunatics in consultation with the medical man in attendance, to sign all necessary certificates, to visit all single patients and patients in private asylums in their districts, to report thereon from time to time to the Commissioners in Lunacy, and so act as district agents for the Commissioners or Deputy Commissioners. When the fact is taken into consideration that the work of the Lunacy Commission has more than doubled of recent years, its numerical strength remaining unchanged, it will be agreed that this aid will not be unwelcome. The salaries of these officers must be fixed to prevent any pecuniary interest in connexion with the certificates, for at present no fee is forthcoming in many instances unless the certificate be signed. The fees now paid for certification would go to meet the expenses of these new appointments. In cases requiring immediate treatment it should be in the power of the medical officer of any asylum to grant an "emergency certificate," under which a patient could be detained for three days, during which time the usual legal course might be pursued. 2. The theoretical and practical study of mental diseases to be made compulsory at the medical schools and by the examining bodies.

III. *Care and Treatment.*—*A.* Pauper patients are congregated in too large numbers in the county and borough asylums for the individual cases to receive the medical attention from day to day that should be allotted to them. It is generally acknowledged that mental diseases are most curable in the early stages, when they require careful treatment. Why then should not patients be received into "hospitals for the insane," of limited size (say, for from 100 to 200 patients), each having a highly qualified medical staff, with clinical assistants, and all the necessary means of treatment? Cases after a fixed time deemed incurable should be transferred to the "asylums," the "homes for incurables requiring no special medical treatment." Heretofore the lunacy laws have been framed on the score of humanity solely, with the result that the insane have steadily increased in numbers "by accumulation." Surely, it would be more economical, more humane, and more creditable to civilisation to endeavour to keep down this accumulation by offering increased facilities for cure. With this end in view, the ratio of medical officers to patients in the hospitals for the insane should be fixed by law, and the large mass of material for practical instruction in mental diseases contained in the county and borough asylums should be placed within the reach of the general body of the medical profession. *B.* Private patients are at the present time largely under the care of medical men who are asylum proprietors. This system, wrong, to say the least of it, from its possibilities of abuse, cannot be defended, and ought to be abolished at the earliest possible date. The asylums of the future for the upper and middle classes will be institutions similar to St. Andrew's Hospital for Mental Diseases, Northampton, and Wonford House Hospital, near Exeter, managed by Committees, and with efficient medical officers having no direct pecuniary interest in the patients.

IV. *Discharge on Recovery or otherwise.*—*A.* For pauper patients. The method of discharge by members of the Committee of Visitors, on the recommendation of the medical superintendent, appears in every way satisfactory. *B.* For private patients. The district medical officer of insanity should have power to order the discharge of any single patient, or any patient from any private asylum in his district, should he deem such a course desirable on account of recovery or otherwise. He should also be in a position to prevent the removal of any patient by his or her friends, when such removal is calculated to be fraught with danger to the patient or other persons.

While purposely abstaining from reference to the many good features of the existing lunacy laws, most of which owe their origin to the philanthropy of the legislators of the past, I would fain, in conclusion, remind the legislators of the present that insanity is but the outward expression of bodily defect or disease, and that if the acknowledged accumulation of the insane is to be arrested, it can be solely by offering legislative aid to medical science, with the hope that a largely increased percentage of cases of recovery will result therefrom.

Kent Asylum, Chartham.

CASE OF SIMPLE MENINGITIS; NECROPSY; REMARKS.

BY ERNEST F. NEVE, M.B. ED., M.R.C.S.,
RESIDENT PHYSICIAN TO THE COWGATE DISPENSARY, EDINBURGH.

I WAS called on Sept. 19th, 1884, to see Mrs. G——, aged thirty-six, multipara, seven children, two miscarriages, four of the children dead. Family history good on father's side. Mother died of consumption. A brother who had served in India suffered from sunstroke, had been intemperate, and died of "brain fever" after a short illness. The patient had delirium tremens two years ago, but since then had been temperate. She was six months pregnant.

On Sept. 17th she complained in the middle of the day of a headache. During the night she slept badly, seemed feverish, and complained of her head. On Sept. 18th she rose early, and worked hard at washing all day. She came home a little after 7 P.M. complaining of the pain in her head, which was worse. She was quite sensible, but had no appetite, did not sleep that night, complained of shivering, and wandered in her speech once or twice. On Sept. 19th she was sensible at 6 A.M. About 10 A.M. she became delirious, and very soon after sat up and began to grapple with the wall. She continued to struggle, but did not speak after 11.30 A.M.

When I saw her for the first time, at 12.30 P.M., she was flinging herself about wildly—one moment throwing herself forward then backwards, then over the edge of the bed, now against the wall, the next moment trying to rise up in bed. Three women of average strength were unable to hold her still. She was breathing very rapidly. The right pupil was found to be contracted, the left of normal size. Large doses of potassium bromide and chloral hydrate were attempted to be given every fifteen minutes. During the administration of this she vomited once, and the bowels were moved. At 2.30 P.M. she was in the same condition, so I placed her under the influence of chloroform. Her temperature was now found to be 101·3° F.; pulse 120 to 128 per minute, irregular but full; respiration 60 per minute. At 3 P.M. the pulse was 88, respiration 60. Ten ounces of urine were drawn off, high coloured, clear, no albumen. Cervix uteri soft; external os patent, internal closed. The hands were flexed and adducted at the wrists, and the thumbs tucked under the fingers. At 5 P.M. I cut off her hair, applied an icebag to the head, and allowed her to recover from the chloroform. The wild movements recommenced, but not so severely as before. Six minims of morphia (inj. hypod.) were now injected hypodermically. At 6 P.M. the temperature was 99·7°, pulse 95 to 100, full, strong, but irregular; respiration 28, and heavy. Pupils, left medium, right contracted, and both immovable to light. Lips rather dry; right knee flexed. At 8 P.M. the pulse was 96, respiration 36. At 10.30 P.M. the temperature was 100·2°, pulse 88, and respiration 28. Moves all her limbs occasionally; opened her eyes once on a bright light being thrown upon them, and rubbed the left eye upon my attempting an ophthalmoscopic observation. Fairly quiet during the night. On Sept. 20th, at 10 A.M., the temperature was 101·2°, pulse 118 to

Digitized by Google

120, respiration 48; left pupil more contracted; movements on both sides of the body, more on left than right; face flushed and conjunctivæ somewhat injected. At 1 P.M. the temperature was 100·2°, pulse 100, respiration 50, coarse râles in throat; moved right arm; legs motionless and flaccid. She now gradually sank; the pupils became almost equal and contracted; by degrees all movements of the limbs subsided; the breathing became more shallow; extremities cold; radial pulse imperceptible; the heart very rapid. At 8 P.M. she expired and death was immediately followed by expulsion of the fœtus and placenta, the membranes being intact.

Necropsy, thirty-eight hours after death.—Dura mater only slightly adherent to skull cap. On removing the dura mater the vessels of the vertex were seen to be much injected. Beneath the arachnoid and over the entire surface of the brain, especially between the convolutions, there was sero-purulent and in some places purulent fluid; pia mater not thickened, but its vessels congested; injection especially marked over the junction of the left ascending frontal and parietal convolutions; at the base of the skull there was half an ounce of sero-sanguineous fluid; the venous sinuses of the base were full of dark semi-fluid blood; the vessels of the base of the brain were healthy; the membranes of the base appeared slightly thickened, especially in front of the pons Varolii and along the Sylvian fissures; in the latter there was a great amount of sero-purulent fluid. Careful macroscopic examination failed to reveal the presence of tubercles. On section the brain-substance appeared soft and its vessels were injected; the two lateral ventricles contained half an ounce of blood-stained fluid, with flocculi of softened brain-tissue.

Remarks.—The etiology of this case is obscure. There may have been some slight tubercular diathesis. The mortality amongst the patient's children was high, and her mother was consumptive; but Mrs. G—— had never manifested this tendency in the slightest degree. She was once intemperate, but not recently so. Intemperance is one of the only well-authenticated causes of simple meningitis.[1] It is possible that, for obvious reasons, the history was incorrectly stated in this respect. The symptoms are chiefly striking on account of their severity. The duration of the illness was very short. The violence of the motor excitement exceeds anything which I have seen or read of in connexion with meningitis. The unconsciousness and absolute silence of the patient in the midst of it all were very remarkable. Vomiting, which is looked upon as a frequent and important symptom,[2] was practically absent. This fact, which was also noticed by Dr. Lewis Smith in a certain proportion of twenty-one cases of meningitis analysed by him,[3] is probably due to its being in these cases a phenomenon of special reflex irritability needing some stimulant, such as food or medicine, to set it up. When this is not given, this symptom will often be absent. The temperature in meningitis, according to Rosenthal, Wunderlich, and Rosenstein,[4] maintains high figures. Tauner (loc. cit.) speaks of it as not very high, "seldom reaching 102° F." This case supports the views of the latter. The tendency to slowing of the previously rapid pulse noticed from the commencement was partly due, I believe, to cessation from violent movement whilst chloroform was being administered. Its final increase was possibly due to increasing pressure upon the brain.[5]

SANITATION AT WOLVERTON.—On the 11th inst. the new sewage works for Wolverton were opened. They were commenced in April of the present year, and their estimated cost was £4467; but it is expected that they will be completed under that estimate. The purification of the sewage is attained by Lomax's quiescent precipitation system.

AT the meeting of the Wrexham Board of Guardians on the 18th inst. a hope was expressed that the advisability of the compulsory notification of infectious diseases in all parts of the United Kingdom would be fully discussed at the next Central Poor-law Conference, and a resolution passed.

AGORAPHOBIA.

BY R. PROSSER WHITE, M.B., M.R.C.S.

IN the wide field of scientific medicine, research and demonstration are gradually hemming in and contracting the circle of functional disorders, and the onus of causation is placed upon some unsubstantial coccus or some undefined catalytic action. Functional disorders, however, do exist, and are perhaps increasing, as is proved by the frequent usage of words expressing derangements without inflammation, or constant structural change, such as neurosis, neurasthenia, hysteria, hypochondriasis, &c., to which category this curious phase of nervous phenomenon, I think, belongs.

B. C——, aged about thirty, a professional gentleman, of active intellectual habits, whose previous health was good and whose family history shows no predisposition to nervous disorders, complains that for the last five or six years he has suffered from a nervous kind of light-headedness, gradually becoming more marked and troublesome. The attacks occur about twice a week, and are brought on by the ideas of space, vastness, height, depth, eternity, or such kindred subjects; and these ideas, however conveyed to the brain, such as the viewing of a large building, or vast area, or in conversation, the description of a voyage, even thoughts of the infinite power of God, or a feeling of loneliness—all and each are able to produce upon him an acute attack which shows itself by pallor of face, a peculiar oppression at the back of the head, palpitation, large drops of perspiration upon the forehead, and a feeling of great dread and exhaustion, and sometimes, as he describes it, a feeling of impending madness. The general condition shows slight tendency to stoutness, with anæmia; the lungs, heart, and kidneys are practically sound. He suffers very much occasionally from bilious attack, as he calls them, but otherwise is not troubled with headaches, tinnitus, deafness, or any stomach derangement. After an attack he feels sleepy and heavy, and sometimes passes a large quantity of urine; he says he feels nervous, and dreads the onset of another attack. He is occasionally troubled with spermatorrhœa, and reflexes of all kind are very sensitive.

These feelings and attacks may sometimes be avoided or lessened in severity by moral determination; deep concentration of thought will enable him to cross an open space or certain places which otherwise induce these attacks of dread; companionship relieves the feeling of loneliness and fear produced by the thought of taking a holiday in a part of the country new to him. The presence of a cart, even a stick or umbrella in the hand, persons, or trees, gives a sense of confidence when walking an unknown road. Cheerful and lively conversation, with a congenial companion, will always ward off the attacks.

This case is, I think, a typical example of that described in 1870 by Benedikt and in 1872 by Westphal, under the term "agoraphobia," and is, I venture to think, a not uncommon form of nervousness, though exceptional in its extreme forms; it is an essentially neurotic, as distinguished from an hysterical, affection.[1] It is rarely described in text-books. Quain's "Dictionary of Medicine" gives only a short article, written by Dr. Fred. Roberts, who does not think the complaint idiopathic, but says "it is sequential to some other condition." What that other condition is he does not say. Dr. Maschede is mentioned as describing a case of clithrophobia[2] in a young man who exhibited giddiness and oppression whenever he entered a small room or narrow space, and was obliged to camp out in the open fields and woods, and only in the depth of winter could he be prevailed upon to sleep in a large and airy apartment with all the windows open. Dr. Maschede also mentions two other similar cases. The author thinks that agoraphobia and clithrophobia ought to be classed under the same head, as in both cases the characteristic symptom is that the patient cannot by any means form an accurate conception of his surroundings.

Dr. Grainger Stewart, in a recent lecture upon "giddiness," thinks that these cases are closely allied to ordinary giddiness produced by what he calls and describes as "contradictoriness of sensory impressions." "Normal

[1] Gulstonian Lectures, by Clifford Allbutt, March 4th,
[2] British Medical Journal, May, 1879.

Digitized by Google

equilibrium is the resultant of normal customary external impressions, and the symptoms of agoraphobia are produced by the absence or clashing of one or more of these impressions." This explanation seems to me hardly satisfactory, as my patient insists very strongly that there is a distinct difference between the giddiness associated with his bilious attacks and the giddiness which accompanies his agoraphobic attacks; again, companionship can hardly affect a man's appreciation of vertical lines, by which Dr. Stewart thinks the patients guide themselves, and also we find that the mental ideas of infinity, vastness, &c., are just as potent to produce the attacks as are external impressions.

To me the case seems essentially a form of mental depression in certain faculties unassociated with delusion and closely allied to what is called simple melancholia. There are disorders of perception; bright light, loud noises, likes and dislikes to persons and things are more pronounced and uncalled for, there is increased irritability to all external impressions, and these are accompanied with some form of deteriorated physical health; but I think the seat of this condition is certainly central, not peripheral. May it not be due to some functional irritation of the cerebral cortical sensory centres, which Ferrier calls the anatomical substrata of ideation?

The prognosis in this case is good, and he has always improved and recovered from his nervousness with the recovery of his usual good general health.

Treatment has been with the object of improving the general health by small doses of cod-liver oil, attention to diet, and the avoidance of such associations as aggravate the disorder. Great relief has been found from wearing a pair of dark-purple spectacles, especially upon bright days. The recumbent position, bathing the head with cold water, or a small dose of some stimulant, will often ward off an attack for some time. The peculiar pain in the back of the head is best relieved by pressure of the hands. A dose of bromide of potassium and strychnia will enable him to mount a hill or do some work which he could not have accomplished and would have shrunk from without it, and he finds he requires a quarter of an hour before the medicine acts. Other medicine he takes from which he is confident he receives benefit—namely, nux vomica, iron, and hydrobromic acid.

Wigan.

THE SURGICAL TREATMENT OF DEBILITY, ASIATIC CHOLERA, ETC.

BY J. R. UHLER, M.D.

A FEW years ago, having a patient with stricture of the œsophagus under my care, whom I was unsuccesafully trying to nourish by the rectum, I determined to take advantage of some of the little pores in the subcutaneous tissue to introduce more liquid into the system. For this purpose a nasal douche, with a two-way cock attached to soft rubber tubes, was employed, and at the end of each tube, where the nozzle is usually placed, the cylinder of a hypodermic syringe, deprived of its piston but retaining the needle, was substituted, making a reservoir apparatus somewhat like an aspirator, with two tubes and no valves. This receptacle was filled with whisky and water and other thin nutritive fluids, and the needles were thrust deeply into the areolar tissue of the extremities, while the reservoir was raised slightly above the level of the body to prevent the entrance of air. The fluid was prevented from escaping by pinchcocks close at the ends of the tubes, but at the moment of insertion a few drops were allowed to flow from the needles to show that it was right, and the pinchcocks were then removed. The reservoir was now raised high enough to permit the liquid to pass readily through the needles by natural flow, giving a constant, gradual supply to the tissues, care being taken not to elevate it too much, so as to avoid undue pressure or large collections of fluid under the skin, the object being only to supply the fluid a little faster than it can be absorbed, and to avoid abscesses. This device worked very well on the first day, affording much relief to the patient; but in the course of time the needles became loose, and larger-sized ones had to be substituted. Since then I have used it a few times as a temporary expedient in the vomiting of pregnancy, coma, phthisis, emaciation, after great loss of blood, and when food could not be swallowed, retained, digested, or absorbed. I have also thought (and find from the Journal of the American Medical Association of August 9th, 1884, that Dr. Todd has suggested the same treatment in a different way) that sterilised artificial serum, composed of the chlorides of sodium and potassium in small quantity, dissolved in distilled water, can thus be supplied to the depleted system in cholera from one or more reservoirs connected with three or four tubes and aspiration needles inserted into the extremities. A better plan, however, for cholera, and one which acts locally, and can be combined with this when necessary, is to fill the peritoneal sac, without distension, with sterilised artificial serum, injected at the temperature of the body by the aspirator or other appropriate instruments. The fluid is thus brought in contact with the other side of the diseased intestines, where it can be withdrawn as wanted, and will, like ascitic fluid, act by pressure, diminishing somewhat the size of the bloodvessels and lumen of the bowels; and, as it is exosmosed, washing away or diluting those low forms of life that are said to be the cause of the disease. The fluid when absorbed will also prevent that tarry condition of the blood which stops circulation, and will not interfere except by dilution with opium, acids, gases, or any other antiseptic remedies that may be thought proper to be applied to the interior of the stomach and bowels. For security, the peritoneum may be cut down upon with antiseptic precautions by an ordinary scalpel, and when it is reached a minute hole be made by pinching up the part and incising it so as to admit the dome-shaped aspirator needle or other purified tube. The mouth of the reservoir or aspirator bottle should be closed by sterilised cotton-wadding, and the wound be antiseptically dressed immediately after the operation. The proper time to fill the peritoneal sac is when the serum is rapidly draining off from the bowels, and before collapse occurs, but I would not hesitate to use it in that condition so long as there seemed to be any prospect of absorption.

Baltimore, Maryland, U.S.A.

EXCISION OF LOWER JAW FOR RECURRENT MYELOID EPULIS.

BY W. ALEX. MACKAY, M.B., C.M. EDIN.

EMILIA DE G——, aged twenty-six, born in Madrid, had the last lower molar tooth extracted in 1877. The extraction was followed by a good deal of bleeding and pain. Three months after she felt a hard painless swelling on the outer aspect of the bone corresponding to the situation of the extracted tooth. This slowly increased till in 1881 it had attained the size of an orange. The patient then consulted Senor Don Enrique Perez Andres, who removed the tumour. In three months the growth had returned in the same place, hard and painless as before, but growing now more rapidly, so that on December 20th, 1883, the left cheek was found tightly stretched over a tumour which entirely surrounded the left half of the lower jaw. The growth extended upward to the articulation, inward half way across the mouth, forward it reached the symphysis, and downwards it projected on the neck. The alveolar border of the upper jaw was carried inwards nearly to the middle line, the teeth of this jaw being received into a deep sulcus on the upper surface of the tumour. Examination of that part accessible from the mouth gave rise to pain, and this part also bled when touched, and was of a bright, fleshy, red colour. The cheek, which was adherent, was so tightly stretched that it had ulcerated at the most prominent point; but the ulcer had healed. Neighbouring glands were unaffected. The patient was of a nervous temperament, with a fast and weak pulse; very anæmic and emaciated, as she could not masticate her food, and had lived for some months entirely on fluids. There was slight congestion at the apex of the right lung. Heart and other organs were healthy. The urine was normal in quantity, and did not contain albumen. Her family history was good, and embraced no instance of tumour.

On Dec. 26th, 1883, the patient being under an anæsthetic, the following operation was performed. Entering the knife at the tempero-maxillary articulation, an incision was carried down along the posterior border of the ascending ramus, round the angle, and along the body of the jaw for

Digitized by Google

about half its length. This was met by a second incision, running down and back through the lower lip, a little to the right of the middle line. Grasping the cheek with the left hand, it was reflected up from the tumour, which then came well into view. Clearing the anterior attachments of the tongue from the bone, the saw was applied at the level of the second incisor tooth of the right side, which had been previously extracted. The lateral attachments of the tongue being severed close to the bone, the temporal muscle was cut at its insertion into the coronoid process, and the jaw being drawn outwards and slightly downwards the disarticulation was easily effected and the mass removed. The facial artery, which was small, the inferior labials, and one or two muscular branches, were ligatured. The large cheek-flap fell well into position, and was retained by silver, silk, and catgut sutures. Placing a slip of lint in the deep incision, a light dressing of protective and boracic wool was applied, and the patient placed in bed on her right side. During the after-dressing the mouth was daily sponged out with a mixture containing equal parts of tepid water and tincture of eucalyptus globulus. A short cough proved troublesome for a few days, but was relieved by inhalations of the same tincture. The temperature did not rise above 102° F., nor the pulse above 120. The wound healed rapily throughout its entire extent, except where a small opening remained, about the middle of the incision, discharging saliva. The patient sat up in bed on the tenth day after the operation, dressed on the fourteenth, and at present continues in perfect health.

Remarks.—The microscope shows a dense fibrous structure containing nucleated spindle cells and groups of multinucleated myeloid or giant cells. The case illustrates the certainty with which these epuli return unless that part of bone from which they spring be removed with them; in the former operation the tumour had simply been cut off, and its site freely cauterised. It also shows well the increased rapidity of growth in tumours reproduced of the fibroid variety. Limitation by the symphysis and by the articulation was well marked, as the growth extended quite to the joint, and forward to the middle line. Although the cheek had ulcerated, the ulcer, not being malignant, had healed. The rapidity and completeness of recovery encourage removal of the largest growths in this region; although, from the size of the tumour, section of the portio dura and consequent deformity were unavoidable.

Huelva, Spain.

A REMARKABLE CASE OF UMBILICAL TUMOUR.

BY J. WYATT PRATT, M.R.C.S., L.R.C.P. EDIN.

CASES of umbilical tumour are not of frequent occurrence, and the following one presents some characters that are unique. Three years ago I attended the birth of a male child whose umbilical cord was of average length but of unusual thickness throughout, and which for the space of an inch and a half from the abdomen presented a dilatation of more than double the diameter of the remainder. The usual ligature was applied just beyond this enlargement. The resulting stump was exceedingly tense and hard. On the ninth day the coverings at the top had sloughed and showed a red granular projection, and in about a month all the outer coating had disappeared, and a firm, smooth, red tumour was left. This was an inch and half in length, pyriform in shape, and attached to the umbilicus by a short but thick pedicle. The outer expanded extremity presented a central orifice, from which more or less constantly a watery fluid exuded. There was no evidence of hernia. The growth did not appear to be painful to the touch, nor even to firm pressure; its surface bled when handled unless treated gently with oiled fingers, and, as usual in such cases, always became more full and vascular when the child cried. Towards the end of the third week feculent matter oozed from the terminal orifice, and this recurred, every three or four days only, for the following month. During the latter period, on three occasions, without any appreciable cause, bright-red blood trickled out from the same aperture, this at several days' interval, and upon the last occasion in considerable quantity. The infant in other respects was healthy, and at the breast thrived well. The tumour was dressed once daily with carbolic oil. When the little patient was seven weeks old, after the last somewhat severe attack of hæmorrhage, I tied a strong silken cord around the pedicle. This was followed by sharp bleeding from the seat of ligature, which was easily arrested by a fold of lint soaked in styptic colloid. A pad and a firm bandage were then applied to the abdomen. The bowels had been relaxed naturally before this treatment. Three days afterwards, upon the removal of the binder, the growth was found detached in a little well of pus upon the lint. The resulting raw umbilical surface was dressed with zinc ointment and a pad, and in a few days more nothing was noticeable except an induration around the umbilicus. Since then the child has continued well. The case is worthy of record on account of the fistulous communication with the bowel, and the tendency to spontaneous hæmorrhage.

Wiveliscombe.

FATAL CASE OF HYDROPHOBIA.

BY MAURICE KNOX,
SURGEON, ARMY MEDICAL DEPARTMENT.

PRIVATE H——, aged twenty-two years, a strong and healthy man, was badly bitten on the exposed surface of the left wrist and hand on May 25th, 1884, by a native dog. The dog was immediately killed by one of his comrades, and the man sent to hospital, where his wounds were washed, and freely touched with nitrate of silver; he remained in hospital twenty-three days. The patient presented himself on the morning of August 13th complaining of pain in his back and shoulders, the result, he said, of throwing a heavy shot. Shortly after admission the symptoms of hydrophobia commenced to develop themselves; he complained of discomfort about his throat, and when he was presented with fluid he started back with a look of horror on his face, became wildly excited, and the muscles of his throat and the muscles of respiration were acted on, producing severe spasms and short quick inspirations. The poor fellow when spoken to made every effort to swallow fluid, or take ice into his mouth, but without success, and his cry was "Take away the water; it will kill me." His skin was cool, and bathed in sweat; pulse 80. Given one-third of a grain of morphia hypodermically, and twenty grains of hydrate of chloral by enema; to remain in a dark room. 6 P.M.: Temperature 99·6°; pulse 80; has had some severe spasms within the last three hours. Given half a grain of morphia hypodermically, and twenty grains of hydrate of chloral by enema; also an enema of eggs and brandy. 11 P.M.: Patient much exhausted; any movement in the room or flash of light produces violent spasm of the muscles of the throat and muscles of respiration; he shrinks away in dread from being touched, is at times wildly excited, imagines there is a dog in the room, at other times talks quietly and sensibly to those about him. Given half a grain of morphia hypodermically, twenty grains of hydrate of chloral by the rectum, and an enema of eggs and brandy. Patient became quite exhausted before morning, and died at 3 A.M. on Aug. 14th. During this case no pain was complained of at the place where the bite had occurred, and there was very little secretion of viscid saliva.

Necropsy, five hours after death.—Rigor mortis well marked. Five scars on back of the left wrist, one on front. Nerves of the forearm apparently healthy. Brain: Weight 41 oz.; the surface vessels contained dark fluid blood; nothing abnormal apparent to the naked eye on section. The blood throughout the body was dark and fluid; nothing abnormal was observed about the mucous membrane of the mouth and throat. The pericardium and heart were normal. Old adhesions on both sides of the pleura and lungs; both lungs full of dark blood. On section the kidneys presented a dark colour, and the spleen was congested. On section the liver showed a dark colour, weight 3 lb. 8 oz. The stomach was quite empty, and the coat appeared to be much thickened.

Bareilly.

A GIFT of £100, from an anonymous donor, has been received by the Secretary of the Swansea Accident Hospital for the benefit of the institution.

NORWOOD COTTAGE HOSPITAL.

CASE OF OVARIOTOMY, WITH HIGH ADHESIONS; RECOVERY.

(Under the care of Dr. JOHN H. GALTON.)

A. C——, aged fifty-eight. The maternal grandmother died of dropsy of the abdomen and legs at the age of sixty. In 1879 the patient first noticed a swelling of the abdomen; she did not observe whether it was one-sided. In May, 1882, she first came under observation, with uniform enlargement of the abdomen to forty-one inches and a half in circumference; no solid tumour to be felt anywhere, universally dull on percussion. The uterus was small, freely movable, and no swelling could be detected on the roof of the vagina. She had at intervals severe attacks of pain in the hypochondria.

On August 11th, 1884, there was great distress from the swelling; the abdomen measured forty-eight inches. To relieve this she was tapped, two pailfuls and a half of coffee-ground-coloured tenacious fluid being drawn off. After tapping, one small solid lump, four inches by two, could be felt in the epigastrium; the rest of the tumour, lobulated and solid to the feel, had shrunk into the lower iliac regions on both sides, and was freely movable.

On Oct. 14th she was admitted into the hospital, greatly emaciated, with an anxious ovarian look. Pulse 92, tongue clean; the abdomen universally distended and dull all over, measuring forty-five inches and a half.

16th.—At 1 P.M. operation was performed, with the assistance of Drs. Miller and Hetley, and Messrs. Sidney, Turner, and Plimmer. Chloroform was administered by Junker's inhaler by Dr. Brockwell, four drachms being used during the operation, which lasted an hour and ten minutes. The slight bleeding in the surface incision of five inches was arrested by torsion of two vessels. There were recent adhesions all round the upper segment of the cyst, very firm to the abdominal wall and intestine, in the right hypochondrium. In detaching these with the finger nail the cyst burst. It was already partially emptied by a Spencer Wells' trocar, but a quantity of shreddy lymph was discharged from the broken cyst, most escaping externally. One omental vessel was secured by torsion. The whole surface of the intestine, uterus, and cyst wall was deeply injected from recent peritonitis. The cysts were drawn forward, and the pedicle ligatured in two portions half an inch from the uterus. The pelvis was well sponged out, and the wound brought together by five thick silver sutures, including the peritoneum. Two superficial sutures were passed at the ends, green protective and eucalyptus gauze dressing, fastened with broad strips of plaster, and a four-tailed flannel bandage were applied. Twenty pints of fluid and three pounds seven ounces of solid were removed. Half a grain of morphia suppository was given. Pulse after operation 82. 7 P.M.: Pulse 106; temperature 103°; perspiring freely; tongue moist; slight twinges of pain in abdomen. Ordered twenty minims of tincture of opium every three hours; only ice to suck. 12 P.M.: Pulse 94; temperature 99°; no pain. Drew off four ounces of urine, much flatus passing per anum.

17th.—11 A.M.: Pulse 94; temperature 102°; respiration 19. Sleeping quietly. No pain or vomiting. To repeat opium every four hours, and to have an ounce of milk and lime water alternately with half an ounce of beef-tea every two hours. 8 P.M.: Pulse 84; temperature 101°; respiration 27.

18th.—Pulse 94; temperature 100·8°; respiration 11; voice strong; says she could take more food. To repeat opium every six hours. No distension or tenderness of abdomen. 5 P.M.: Temperature 98·2°. 8 P.M.: Pulse 84; temperature 99·4°. Has had twinges of pain in lower part of abdomen. Beef-tea slightly returns. To go on with milk and lime-water. Has feeling of faintness. To have half a teaspoonful of whisky every two hours.

19th.—Pulse 82; temperature 98·6°; no pain; slept well; hungry; had half a pint of beef-tea during last twelve hours; wound dressed, perfectly healthy; only slight oozing between two lower sutures; free from smell; abdominal walls flaccid with abdominal respiration and free peristalsis; had three tablespoonfuls of soft boiled rice with beef-tea. 9 P.M.: Pulse 88; temperature 100·6°.

20th.—Pulse 84; temperature 98·6°. 9 P.M.: Pulse 86; temperature 98·2°. To repeat opium at night only. Had rice with beef-tea; bread-and-butter and tea.

21st.—Pulse 84; temperature 98·2°. 6.30 A.M.: Passed urine naturally. 7.50 A.M.: Has slight shivering; temperature 101·2°; wound dressed, healthy; no discharge; surface union firm throughout; abdominal respiration; no tension of abdominal muscles anywhere; bowels acted naturally with solid motion at 7 P.M. 6 P.M.: Pulse 84; temperature 97·8°.

23rd.—Pulse 84; temperature 97·8°; wound dressed; entirely healed; removed all sutures; dressed with dry lint and strapping, and four-tailed bandage; bladder distended; drew off a pint and a half of urine; during the day thirty ounces of urine were, in all, passed. 8 P.M.: Pulse 84; temperature 99·4°. An enema of warm water brought away a quantity of solid motion.

25th.—Pulse 94; temperature 97·8°. Urine contains mucus and pus. Ordered four ounces of port wine.

26th.—Pulse 84; temperature 97·8°. Two natural motions. Two small bedsores formed from the pressure of the bandage folds. Ordinary diet.

29th.—Pulse and temperature normal. Urine still loaded with muco-pus. Ordered the following mixture, a drachm and a half of dilute nitro-hydrochloric acid, three drachms of glycerine, and eight ounces of the decoction of pareira; an ounce to be taken three times a day.

30th.—Applied abdominal belt, with pad, over wound.

Nov. 3rd.—Out walking. The urine improved; bedsores were healthily healing, and on Nov. 11th she was discharged cured.

Remarks.—The existence of the solid mass above, the history of frequent severe pains in the upper abdomen, and the great emaciation and weakness, constitute an apparently unfavourable case. The difficulty of separating the high adhesions on the right side, and the bursting of the cysts during the operation, made success unexpected; but the patient recovered without a bad symptom. Again, we notice the free discharge of fluid by perspiration and urine after the operation, as if when the cyst is removed, the drain of fluid to which the circulation is accustomed must be kept up by other channels.

PUBLIC HOSPITAL AND DISPENSARY, SHEFFIELD.

PNEUMONIA; CONVALESCENCE; GANGRENE OF BOTH FEET; PARALYSIS OF LEFT ARM AND LEG, AND OF RIGHT SIDE OF FACE; CHEYNE-STOKES' RESPIRATION; DEATH; NECROPSY; CLOTS IN RIGHT MIDDLE MENINGEAL, RIGHT POPLITEAL, AND LEFT ANTERIOR AND POSTERIOR TIBIAL ARTERIES; HÆMORRHAGIC INFARCT IN UPPER LOBE OF RIGHT LUNG.

(Under the care of Mr. PYE-SMITH and Dr. PORTER.)

FOR the following interesting notes we are indebted to Dr. Sinclair White, F.R.C.S. Eng., house-surgeon:—

William W——, a cooper, and addicted to drinking beer to excess, but fairly healthy and of robust appearance, was attacked with pneumonia about two months prior to his admission to the Sheffield Public Hospital. He convalesced from the attack, and went to the seaside to recruit his strength; while there he lost his cough, and was restored almost to his usual health. On August 18th, 1884, while walking across the room he suddenly felt pain and numbness in the legs and feet, and went at once to bed. In the course of a few hours the feet became cold and lost sensation; next day there was complete loss of motor power in the feet, and the tissues were œdematous. On Aug. 20th the œdema had extended half way up the legs, and the toes, which were previously white and bloodless, assumed a purplish hue.

He was admitted into the hospital on Aug. 22nd; his condition was then as follows. Both legs and feet were quite

Digitized by Google

cold, destitute of feeling, and slightly swollen; the right foot, in its anterior half, was of a dark purplish colour, and the skin presented several bullæ; the toes of the left foot were of a similar colour. The femoral arteries could be felt pulsating in the groins, but no pulsation lower down could be made out. He complained of considerable pain in the legs. The lungs were everywhere resonant and the breath sounds natural; there was no cough and no dyspnœa. The action of the heart was tumultuous, the heart sounds normal, and the pulse 75 per minute and regular. The evening temperature was 101°, that of the morning 100°. The urine was somewhat scanty, but presented nothing abnormal. The tongue was clean and the appetite good. He denied having had syphilis. He was ordered a liberal diet, a moderate amount of stimulants, and half a grain of opium three times a day. The feet and legs were swathed in cotton-wool. The progress of the case is related in the following notes, which were taken from time to time.

August 26th.—Little alteration, the œdema of the legs has subsided slightly.

28th.—Sensation and warmth extend as low as the lower third of the legs. The gangrene is stationary. Sleeps badly at night.

September 1st.—Condition of legs unchanged. Was slightly delirious during the night.

3rd.—Was very delirious during the night and got out of bed. The pulse is irregular. There is dyspnœa. Numerous mucous râles are audible over both lungs.

4th.—Patient is much worse, the night delirium persists. There is complete paralysis of the left arm and leg and slight paralysis of the right side of the face. The pulse is irregular and intermittent. Cheyne-Stokes' respiration is present. Consciousness is impaired.

6th.—Has been semi-conscious for the last three days; the paralysis persists, so does the Cheyne-Stokes' respiration, the latter is very marked, the abnormal cycle occupies a space of 67 seconds, the ascent is made up of 33 respirations, which become deeper and quicker until the climax is attained, the time occupied by the ascent is 40 seconds; the descent is made up of 10 respirations and occupies a period of 15 seconds, the last few respirations being very shallow; the pause occupies a period of 12 seconds. The various phases of the cycle succeed one another with great regularity, almost always in the middle of the ascent the patient utters two or three groans. 8 P.M.: Pulse very weak, there is much dyspnœa. The respirations have ceased to be of the Cheyne-Stokes type. There is complete loss of consciousness. The sphincters have ceased to act.

Death occurred on the morning of September 7th.

A post-mortem examination made ten hours after death revealed the following condition. The brain was unusually soft, especially on the right side; there was a firm clot in the right middle cerebral artery. The mucous membrane of the bronchial tubes was much congested and covered with mucus; there was a large hæmorrhagic infarct in the upper lobe of the right lung. The heart weighed eighteen ounces; its lining membrane was smooth and glistening, nothing resembling ante-mortem clot or vegetation was anywhere visible; valves healthy; there were two yellowish elevations—commencing atheroma—on the lining membrane of the aorta near its commencement, the rest of the aorta and its primary branches were normal. Liver large and slightly fatty. Spleen normal. Kidneys intensely congested, evidence of commencing cirrhosis, shown by adherent capsule and puckered exterior. Femoral arteries healthy. On tracing their continuity downwards a firm clot was found in the right popliteal artery, and similar clots in the left anterior and posterior tibial arteries. The clots were of considerable length, they completely obstructed the arteries, and were adherent to the lining membrane. The arteries above the clots were empty, below the clots they were full of dark fluid blood. The veins down to the seats of obstruction were normal. No difference could be made out between the centre and the periphery of the clots.

THE man who, being an inmate of the County Asylum at Mickleover, stabbed Dr. Murray Lindsay, the medical superintendent, in three places, has been committed for trial. Dr. Lindsay was, we are glad to say, sufficiently recovered to be able to give evidence at the examination.

VACCINATION GRANT.—Mr. George Lowther has been awarded the Government grant for efficient vaccination in the east district, Kingston-upon-Hull (fourth award).

Medical Societies.

WEST LONDON MEDICAL AND CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Nov. 7th, Mr. F. Lawrence, President, in the chair.

Mr. BERNARD PITTS read a paper on Foreign Body in the Air-passage, followed by abscess in the lung, with recovery. A boy, aged nine years, was brought to St. Thomas's Hospital on Dec. 29th, 1880, in an insensible and asphyxiated condition. He had been seized with difficulty in breathing fifteen minutes before while eating chestnuts. Tracheotomy was performed in the casualty room the moment he was seen by Mr. Pitts. Hæmorrhage was free, and no relief was afforded until a catheter was passed down the trachea, a foreign body was then suddenly coughed beyond the tracheal opening into the larynx, and the bleeding at once ceased, and air began to enter the chest freely. The foreign body, consisting of a portion of a chestnut about the size of a dice, was easily extracted from the larynx by forceps introduced through the wound. The next day there were evident signs of the presence of a further piece of chestnut in one of the divisions of the right bronchus, and an attempt, under chloroform, was made to dislodge it by inversion of the patient, but failed. The edges of the trachea were fastened by sutures to the margin of the skin wound. In a few days there were signs of the consolidation of the upper part of the right lung, and a condition resembling acute phthisis became established — high temperature, sweating, emaciation, copious expectoration of a very offensive muco-purulent character—with the physical signs of a larger cavity opposite the second intercostal space. The boy, however, made a good recovery, and, after nearly three months' acute illness, left the hospital for a convalescent home. He was examined six months later, when the cavity was found to have contracted, and the boy to have regained his usual health, there being now no evidence of former mischief, except a slight flattening at the second and third intercostal spaces on the right side of the chest. Mr. Pitts referred to other cases to show how soon abscess of lung may follow the obstruction of a bronchial tube by foreign body; and, in conclusion, made some general remarks on opening the air-passage in cases of sudden emergency.—Dr. THUDICHUM referred to impaction of a tooth giving rise to consumption, ending in death, and Dr. CHAPMAN to a case where a shot was impacted, giving rise to phthisical symptoms.—Mr. PICK referred to some remarkable cases, one especially where a piece of tobacco-pipe became impacted in the bronchus, the child breathing through it.—Dr. BECKINGSALE and Mr. WEISS mentioned cases, and Dr. TRAVERS strongly recommended exploration of the upper part of the larynx by the finger before operating.—In reply to Mr. PICK, Mr. PITTS stated that no portion of the impacted piece of chestnut had been found in the sputum, but that it had probably slowly disintegrated.

Mr. M. THOMPSON read a case of Retention of Urine, with fever, followed by death. On Sept. 11th E. E——, aged twenty-two, came to the West London Hospital with twenty hours' retention. His doctor had tried to draw off his urine. The patient had had a stricture three years, several occurrences of retention, and practised self-catheterism. He was a healthy-looking man, seemed in great pain, bleeding from the urethra, and bladder distended. No. 15 French catheter was arrested 5 inches down the urethra, and felt rough, and discharge of blood followed. Patient was sent to bed, a hot bath (100° F.) was given; quinine, opium and hyoscyamus were ordered, after which three pints of urine (free from blood) were drawn off through a railroad catheter passed over a long piece of catgut. On the 12th he did well, excepting that he appeared exhausted, passed water fairly until the following evening (twenty-four hours from admission), when rigors set in, with temperature 105·6°. Ice was applied to the head and bladder region, sulphate of quinine, twenty grains, were given in three doses at intervals of an hour, and in three hours the temperature was 101°. At midnight, on account of feebleness of pulse and coldness of extremities, ice was discontinued, and two ounces of brandy were given in hot water every two hours. On the 13th vomiting set in, with increasing collapse and cessation of urinary secretion. Lumbar poultices and hot air baths with stimulant enemata were used; but on the 14th,

Digitized by Google

after increasing collapse and cyanosis, the temperature rose to 107°, and death ensued. At the post-mortem examination general subcutaneous emphysema was observed, and endocarditis; a slough in the urethra at the seat of stricture; false passages and pus in prostate. Bladder contained one ounce of urine; kidneys healthy. Mr. Maitland Thomson remarked that the case illustrated the danger of introducing micro-organisms into false passages when self-catherisation was practised. The urine, too, acting in the false passages, might have caused an inflammatory focus, resulting in systemic infection.—In the discussion which ensued, Dr. ALDERSON related a case in which the ferret catheter (Teevan) was successful.—Mr. LLOYD would in most cases rather relieve by a small catheter than pass an overslíding one.—Dr. THUDICHUM, referring to the emphysema, judged the case was one of uræmia, an opinion which was confirmed by Mr. DUNN, who made the post-mortem, and remarked on the ammoniacal nature of the emphysematous gas.—Dr. PATMORE, when bleeding occurred, enjoined perfect rest, and five-grain doses of quinine to ward off fever.

Mr. NOBLE SMITH read a paper on the objects of the Medical Sickness Annuity and Life Assurance Society, and Mr. Radley, the secretary, attended to answer any questions put by members.

Dr. CHAS. GOOD read a case of Gastric Ulcer ending in perforation and sudden death. Miss L——, aged twenty, since having an attack of uterine inflammation, three years since, had been in fair health, with the exception of constipation and flatulence, with capricious appetite. When seen at 7 P.M. on Sept. 25th she was suffering from acute pain in the umbilical and hypogastric regions, slight mucous vomiting, rigidity of abdominal muscles, with tympanites, tongue clean and indented. Temperature 99°; pulse 84, small and hard. She had taken castor oil, and Dr. Good ordered hot fomentations and an opiate mixture. At 4 P.M. on the 28th she was taken suddenly worse, and died before Dr. Good's arrival. The abdomen was distended and tympanitic. Necropsy, thirty-six hours after death, revealed the following conditions: mesentery thickened, and intensely hyperæmic; two folds of intestine in contact with the mesentery, inflamed; a circular punched-out ulcer, one inch and a half from the pylorus on the anterior surface of the stomach. The ulcer had indurated edges and was as large as a threepenny piece. No extravasation of blood or adhesions. Gastric mucous membrane pale. Dr. Good remarked on the medico-legal aspect of the case. The clinical history did not point to gastric ulcer. From the sudden death the case might have been perforating duodenal ulcer, rupture from enteritis, or the sudden fatal termination observed in some cases of peritonitis. Sudden death from nerve shock without hæmorrhage was very rare.

Mr. H. PERCY DUNN showed a specimen of congenital contraction of a portion of the Colon, Sigmoid Flexure, and the Rectum, from a patient aged sixty-five.

ACADEMY OF MEDICINE IN IRELAND.

THE opening meeting of the Medical Section was held on Nov. 21st.

The PRESIDENT, having congratulated the Academy on its highly satisfactory position, entered upon the discussion of some of the relations existing between medicine and law, pointing out their frequently unsatisfactory nature. In passing, he touched upon the position of medical men as experts, as witnesses, and as defendants, and proceeded to discuss their relations with the Court of Chancery, both as regards their attendance on minors and lunatics and as claimants for settlement of accounts paid through the Court. He illustrated, by cases arising within his own experience, the difficulties met with first from the non-payment of these accounts through the fault of officers of the Court, and, secondly, by their arbitrary reduction of fees.

Dr. WALTER G. SMITH read a communication on the various forms of Lupus, which he illustrated by plates. On the motion of Dr. BANKS, seconded by Dr. GORDON, the discussion on Dr. Walter G. Smith's paper was postponed to next meeting, in order to give Dr. Bernard of Londonderry an opportunity of reading a communication.

Dr. WALTER BERNARD (Londonderry) related the clinical history and exhibited the morbid specimens of a case of prolonged Anuria occurring in a man aged seventy-five years. In December, 1883, micturition became more frequent. In February, 1884, epistaxis and hæmaturia occurred, accompanied by diarrhœa and febrile symptoms. In May the hæmaturia recurred, and between June 6th and 17th complete suppression of urine existed, curiously without any inconvenience to the patient. When the flow of urine was re-established the amount passed averaged 125 to 140 ounces. Suppression of urine set in again on July 4th and 5th, and on the third day he passed bloody urine. In August a tumour was detected behind the pubes. He rapidly wasted and died on Sept. 13th. The post-mortem examination was held eleven hours after death. The uro-genital organs were removed. Mr. Shattock reports having found soft carcinoma of the prostate, bladder, and liver; both ureters dilated. No carcinoma existed in the substance of the kidneys.—The PRESIDENT said this was the first time he had heard of total suppression of urine lasting eleven days without immediate fatal results. It was difficult to understand how it could have taken place for such a length of time without uræmic poisoning.—Dr. ABRAHAM observed that the microscopic specimens were the most beautiful he had seen for some time of morbid growths in the bladder and prostate. As regards the origin of the growths he would scarcely venture an opinion; there were several cells and nests of cells which were extremely similar to the cells of the epithelium of the bladder. He agreed with the remark as to the extreme rarity of carcinoma of the prostate; indeed, having seen a large number of tumours, he had only come across a single case which Mr. Martin had.—Dr. FINNY expressed his satisfaction with Dr. Bernard's remarkable paper. The pathological conditions to which he had alluded were of great rarity. The clinical aspect of the case was also unique—that suppression of urine could exist for so many days without remarkable symptoms. The explanation that it must have been from some nerve cause was likely to be the true one. Where complete suppression of urine took place head symptoms were extremely rare; but urinary fever and uræmic poisoning were not. In the absence of pathological change to account for the suppression of urine for so many days, they must look to a nerve origin.—Dr. H. KENNEDY, referring to the duration of the anuria, said he had in cases of cholera frequently seen patients recover after four days, and once after five days, and the recovery was apparently due to the vomiting. Even when the primary symptoms of cholera had subsided, the vomiting went on, and the patients recovered; so that vomiting seemed to be a vicarious effort on the part of the system to keep life going. He did not know that there was any connexion between the malignant disease and the anuria. Any cases he had seen were not connected with malignant disease, and the case under consideration was in that respect uncommonly remarkable.—Dr. BERNARD having briefly replied, the section adjourned.

CAMBRIDGE MEDICAL SOCIETY.

AT a meeting of this Society held on November 7th, Mr. J. H. HOUGH, describing a case of Puerperal Eclampsia, said he was called last May about 1 P.M. to see a woman who was in strong convulsions; she was about six months and a half pregnant. He sent up two draughts each containing twenty grains of bromide of potassium, and called as soon as possible; he found her lying across the bed nearly nude, pulse quick (120) and feeble. She was comatose, though aroused for a moment on being spoken loudly to and shaken; teeth clenched, eyes open and staring vacantly. Moving her into a better position, he proceeded to make a vaginal examination, but the instant he introduced his finger another violent spasm came on. He at once put her under the influence of chloroform, a cork being wedged between her teeth, and a vaginal examination made. The os uteri was fully dilated, the membranes had ruptured (no doubt during one of the convulsions), and a head presentation was made out very high up. A drachm of liquid extract of ergot was given; she was then quiet for half an hour, when, a convulsion coming on, chloroform was again administered; the fit at once ceased. After an hour's interval, as labour had advanced but a very little, he gave another dose of the ergot and the pains soon after this became regular. Chloroform was exhibited at each pain, which by keeping one hand on the abdomen was easily ascertained. After three hours a very violent spasm came on, and it seemed at first as if the chloroform had lost its effect, but persevering with it the spasm soon disappeared. Half an hour after the child was

Digitized by Google

born alive, and there was no trouble with the placenta; and with the exception of one slight fit no other convulsion occurred. Mr. Hough had not the slightest doubt that the convulsions in this case were due to anæmia. The patient had been in actual want for some time during her pregnancy, and was pale and emaciated. There was but the slightest trace of albumen in the urine; the bowels were not loaded, and the pulse was always quick, rapid, and small. After the first dose of bromide, excepting the two doses of ergot, nothing was given by the mouth, so that there should be no source of irritation to produce the spasms, which yielded readily to the chloroform each time they appeared.

Dr. EASBY related a case of Puerperal Eclampsia seventeen days after labour. A delicate woman, aged twenty-four, was delivered by him on Nov. 27th, after an easy labour, of a female child. It was her second confinement, and she made a good recovery. On Dec. 13th he was asked to see her, and found her suffering from a severe cold and constant frontal headache. The next morning he was sent for hurriedly, as she had had several fits. He found her in a semi-comatose state, pulse 60, temp. 99°. The bowels had not acted, and she had not passed any urine. He prescribed twenty grains of chloral, and she had no further fit until noon. At 3 P.M. he found her about the same; a little urine had been passed, sp. gr. 1020, and containing one-fourth of albumen. At 4 P.M. and 6 P.M. two more slight attacks occurred; the dose of chloral was repeated after each, and a turpentine enema was given. At 8 P.M. she had a violent convulsive attack, with twitching of the right arm and leg, and in five minutes another and worse attack. A catheter was then passed and a pint of urine drawn off, and a third of a grain of tartrate of morphia given hypodermically. She slept well, and there was no recurrence of the fits. There was some headache for a day or two afterwards, but she made a good recovery, and the albumen in the urine disappeared. Dr. Easby remarked that convulsions usually occurred before or during labour or shortly after, and after careful search he had only been able to find records of one case in which so long as seventeen days had intervened. With regard to treatment, he placed most faith in morphia injections.

Dr. BRADBURY showed some Bronchial Casts from a case of Plastic Bronchitis. A young man, aged nineteen, who consulted him in August last for diarrhœa and pain in the stomach, informed him that he used occasionally to expectorate these casts, accompanied with a little blood. He complained also of some pain in the chest, and a double bruit was audible over the heart, the diastolic most marked to the left of the sternum. Nothing abnormal was heard in the lungs. The specimens had been kindly sent to him by Mr. Edwards, of Furneaux Pelham, and were preceded by some dyspnœa and cough. Dr. Bradbury referred to Dr. Clymer's analysis of forty-four cases; it appeared to depend upon some diathetic condition, either scrofula, gout, or rheumatism, but it was occasionally complicated with aneurysm. The best treatment was ammonia and iodide of potassium.

LEEDS AND WEST-RIDING MEDICO-CHIRURGICAL SOCIETY.

AT the ordinary meeting held on Dec. 5th, Dr. Bell, the President, in the chair,

Mr. HEWITSON read a paper on the Connexion of Sick Headache with Astigmatism. He showed several patients in whom severe periodic headaches, accompanied by vomiting and visual disturbances, entirely ceased when they had been supplied with suitable cylindrical glasses. The patients were neurotic subjects, and the headaches, though almost constant in some instances, were aggravated by any special use of the eyes, such as reading or fine sewing. In some cases temporary relief was obtained merely by the use of atropine. In the discussion Dr. S. C. Smith, Dr. Allbutt, Mr. S. Snell, Dr. Jacob, and Dr. Hutchinson took part.

Dr. BARRS showed a case of Athetosis. Hemiplegia had occurred on the side several years ago, but the movements of the fingers were not confined to that side. In reply to some remarks by Dr. Allbutt on the possible peripheral origin of the movements, he upheld the central nature of the lesion as evidenced by the want of wasting and degeneration, and the electric reaction of the muscles.

Professor JESSOP exhibited a male patient, aged fifty, upon whom on October 2nd he had operated for Fæcal Fistula by abdominal incision and intestinal resection. The fistula, which was situated on the right side above the middle of Poupart's ligament, and had followed upon an operation for strangulated inguinal hernia in March last, was very patent, and allowed almost the entire intestinal contents to escape. In July an attempt to close the opening by a plastic operation had failed. The abdomen was opened by an incision about three inches long extending upwards from the fistula. The bowel, emptied by previous starvation, was detached from the abdominal wall and withdrawn, so as fully to expose the large irregular opening from which the gangrenous coil had been detached. It was now seen to be the ileum which was involved, and the opening measured in the length of the gut about an inch and a half, whilst it extended to within a quarter of an inch of the entire circumference. The edges having been pared, and a portion of the free margin of the distal end of the bowel, wasted by disease, cut away so as to equalise the two mouths, a series of six-and-twenty Chinese silk interrupted sutures was introduced, care being taken to oppose serous surfaces all round. The bowel was then returned, and the abdominal wound closed by deep wire sutures, as after ovariotomy. The progress of recovery was uninterrupted, and is now complete. In the discussion Mr. Hodgson Wright, Dr. Barr, and Dr. Jacob took part.

Dr. FARQUHAR gave details of a case of Phlegmasia Dolens, of which the broad features were its severity and erratic course, the swelling and inflammation having invaded both limbs twice alternately. The subject was a primipara a fortnight after confinement, which was premature, and accompanied by considerable hæmorrhage. Iodine and blistering were the most successful remedies. The pyrexia was high and constant. There was a crisis, when enemata, nutrient and purgative, with morphia and atropine under the skin, turned the scale favourably. Dr. Farquhar remarked on the consensus of opinion as to the insufficiency of research so far, with a view to discover the intimate course of this disease. Some insisted on a companionship with erysipelas, but such an alliance was inapplicable in all the cases he had seen. The industry of our workers in micro-organisms as pathogenic agents offered the likeliest solution of the causation of this obscure ailment. — Dr. BRAITHWAITE pointed out the part taken by the lymphatics in cases of this kind, and said he had observed the more frequent occurrence of thrombosis in cases where labour was much prolonged and the cervix uteri most usually bruised or lacerated.

Dr. SOLOMON C. SMITH read a paper on Massage, Faradisation, and the Zander Movement Cure, in which he attributed the good effects of each of these methods of treatment to their action in assisting the circulation through the lymph canalicular system and the flow of blood through the capillaries and veins; and he advocated their more extended use, not merely in local conditions, but in all cases in which, either from want of will or of power, large tracts of muscular tissue remained unused.—Dr. HUTCHINSON thought the principal use of these methods was to stimulate the circulation in the excretory organs, and thus to get rid of effete materials.—Dr. ALLBUTT, referring to the good effects obtained by nerve vibration, thought much of the effect to be due to reflex stimulation of the peripheral nerves, especially as most cases profiting by this form of treatment were emaciated, and not needing increased elimination.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY

A MEETING of the above Society was held at Rotherham on Nov. 20th, Mr. W. A. Garrard, President, in the chair.

Dr. KEELING showed a Suppurating Ovarian Cyst, removed from a patient in the Jessop Hospital.

Mr. SIMEON SNELL introduced a girl, aged between eight and nine years, for whom on May 23rd, 1878, he had Enucleated the Left Eyeball on account of Glioma of Retina (eyeball removed six and a half years since; no recurrence of disease). The disease had apparently existed some months, but was confined to the posterior part of the globe. Microscopic examination confirmed the diagnosis as to the disease being a glioma. Now, after the lapse of six years and a half, there had been no recurrence. Mr. Snell briefly alluded to the question of diagnosis in these cases, and mentioned that the specimen in this instance was com-

Digitized by Google

pared with another case at the time, in which recurrence took place and death.

Mr. GARRARD introduced a patient, five months old, who had a Patent Urachus of unusually large size; the tube was as large as a man's urethra; the umbilicus looked like a ripe strawberry. A full-sized catheter could be passed into the bladder; urine always came through the opening, and sometimes all the urine was passed this way. A fortnight previously he had ligatured the protruding portion with gut, and, after freely paring the edges of skin all round, had closed the orifice by means of quilled and superficial sutures, including the thickened parts around the urachus. The umbilicus is now practically healed, and no urine has escaped since the operation.

Mr. GARRARD also introduced a man, aged thirty-two, suffering, as he thought, from Mollities Ossium, affecting the ribs and spine, and had done so for two years.

Mr. B. WALKER introduced a man, aged thirty-four, a miner, who had been injured by a fall of coal two years previously. On his admission into the Rotherham Hospital on April 25th, 1884, several sinuses, one of which led down to necrosed bone, in the patella were found; others communicated through the posterior part of the joint. On April 29th the knee joint was laid freely open and explored, with the view to probable amputation. No dead bone was found, with the exception of the patella; and, as the rest of the joint appeared to be not in a hopeless condition, it was decided to excise the whole of the patella. This was accordingly done, the wound was plugged with lint saturated with carbolic oil, the joint enveloped in salicylic wool, and kept at absolute rest by means of a back splint. Erysipelas attacked the limb a few days later, and did not entirely disappear until May 30th, since which time he was troubled with small cold abscesses travelling up from the foot, each one higher than its predecessor. On July 18th he had a sound but perfectly stiff joint; on Aug. 18th he could bear a little weight on the leg, and at the present time (Nov. 20th) he could get about much better. The President, Mr. Barber, Mr. Pye-Smith, and Mr. Jackson joined in the discussion.

Mr. ARTHUR JACKSON showed a specimen of the Cellular Uterine Polypus which he had removed on Oct. 2nd, 1884, from a woman aged twenty-seven. She suffered from dysmenorrhœa from April, but did not apply for medical aid till June, when menorrhagia set in. This continued till Oct. 2nd, when the polypus was removed. The apex of the tumour was close upon the perineum. There was no difficulty in tracing the pedicle to the left wall of the cervix, and removal with a pair of forceps was easy. There was no hæmorrhage, and she gradually recovered her strength. Remarks were made on the specimen by Dr. Keeling, Dr. Dyson, the President, Dr. Banham, and Mr. Favell.

Mr. ATKINS showed the Organs from a case of Hydatids of Liver, Spleen, &c. in the abdominal cavity in which death had resulted from persistent vomiting, due to pressure on the colon. The man, aged thirty-two, was admitted under the care of Dr. Bartolomé, at the infirmary, in an extremely emaciated condition; his symptoms—vomiting, abdominal tenderness, and difficulty in micturition—had only come on during the last three weeks; he was constipated, only passing small hard fæces occasionally, with a large quantity of slime. On examination, his abdomen was found irregularly swollen and tender; there was a well-defined mass in the cæcal region, giving a soft doughy sensation; there was also a transverse mass of dulness in the umbilical region, exactly in the position of the transverse colon; dulness was also found in the right lumbar region, but the lower edge of the liver and spleen were hidden by an immensely dilated stomach. The man died the day after admission; and at the autopsy the cavity was found a mass of hydatid cysts, one large one in the liver, and the spleen itself was simply a sac, five or six times its normal size, full of smaller cysts. Several of the cysts were suppurating. Mr. Jackson, Mr. Barber, Dr. Keeling, and Dr. Banham, joined in remarks in the case.

Mr. BALDWIN exhibited a man, shown by him at the corresponding meeting last year, with Exophthalmic Goitre. Then he suffered from inability to lie down, but he had been hop-picking this year, roughing it, and returned much better; drank cider, and can now lie on his side.

Dr. BANHAM read a paper on Otology in relation to General Medicine, in which attention was drawn to the frequent occurrence of ear symptoms, tinnitus, deafness, and vertigo, apart from any disease of the organs of hearing. The important relations existing between ear disease and certain constitutional conditions, as scrofula and tuberculosis, were insisted on, and attention drawn to the serious secondary affections of the brain arising as the result of disease of the middle ear. The opinion was expressed that some steps might with advantage be taken by the various examining Boards to secure the attendance of medical students upon the practice of the special departments. In the discussion which ensued the following gentlemen took part: Mr. Walker, Mr. Snell, Dr. Dyson, Mr. Pye-Smith, and Dr. Morton.

MIDLAND MEDICAL SOCIETY.

A MEETING of this Society was held on Wednesday, November 19th, the President, Mr. T. F. Bartleet, F.R.C.S., in the chair.

Dr. SAUNDBY read a paper on Kussmaul's Coma based upon two recent cases. He described its symptoms, drawing attention to the peculiar character of the dyspnœa as constituting a distinguishing feature of pathognomonic significance, and especially insisted upon the fact that this form of coma is not restricted to diabetes, one of the cases related being an example of its occurrence in advanced renal disease. He referred to the various theories which have been advanced to explain it, and stated precisely the exact position of the acetonæmia question. He explained the methods used for testing for acetone and showed Le Nobel's test with nitro-prusside of sodium and ammonia. In his opinion the symptoms were due to the action of some poison nearly allied to acetone. He referred to Minkowski's suggestion that they might be the result of dealkalisation of the blood from the presence of β. oxybutyric acid or some other acid in great excess. After discussing the predisposing and exciting causes and the diagnosis, he pointed out that it is not invariably fatal, that treatment in the early stages should be eliminatory, by purgatives if the bowels can be got to act, and that later on the intravenous injection of a neutral saline solution should be tried, as the result in one of these cases was to restore animation for the time, and where recovery is possible more permanent results might be expected. Unfortunately in that case the alterations of structure were too profound to permit a hope of life being prolonged.

Mr. PRIESTLEY SMITH exhibited a boy, aged eight, whose left Crystalline Lens had become dislocated spontaneously on to the front surface of the iris. It was perfectly transparent, and presented the bright-golden reflex from the margin always visible in such cases. It retained a partial attachment to the suspensory ligament. The cause of the displacement was a congenital imperfection in the suspensory ligament, and this was present in the other eye also. The dislocated lens had, a few days previously, fallen backwards through the pupil while the eye was under examination, and had for a while been retained there by the use of eserine. It had now again fallen forwards, and would probably have to be removed by operation.

Dr. SUCKLING showed a man suffering from Complete Paralysis of the Left Arm. Eight years previously the patient had a sunstroke on board ship; he fell from the deck into the stoke-hole. In falling he caught his left arm over a handrail and dislocated his shoulder. He was unconscious for a considerable time after the fall. Dr. Suckling pointed out the great value of electricity in diagnosing the cause of the monoplegia, and was of opinion that it was due to a cerebral lesion, acquired at the time of the fall, in the region of the ascending frontal and ascending parietal convolutions on the right side. The following circumstances, in his opinion, proved the cerebral nature of paralysis:—1. Faradaism and galvanism to the nerves, motor points, and muscles of the left upper extremity showed only slight diminution in response; there were no qualitative changes. 2. Sensation was perfect and the reflexes were increased. 3. There was late rigidity in the muscles of the hand. 4. The man suffered from headache, especially on the right side; he was deaf, but worse in the right ear, and also had attacks of vertigo.

Mr. EALES exhibited a young woman, aged twenty-two, on whom, six months previously, he had operated for Extreme Divergent Strabismus of fourteen years' duration, caused by an unsuccessful operation (not by himself) for strabismus convergens. The internal rectus of each eye had been redivided and brought forward to its proper position, tenotomy of the opposing external rectus being at the same time performed. The result, which was most successful at

Digitized by Google

the time, was maintained, the patient's eyes being now quite parallel as regards their visual axes, while excursions in all directions were free, and convergent power well sustained in near vision.

A meeting of this Society was held on December 3rd, the President, Mr. T. H. Bartlett, F.R.C.S., in the chair.

Mr. HASLAM read a paper on Medical Education, in which the question of what education a student should have before commencing his medical studies was discussed. Many students at present enter at a hospital with little or no knowledge of such subjects as chemistry, botany, or physics, and are consequently unable at once to study with advantage either physiology or chemistry. Moreover, they have not learnt how to work at scientific subjects, and so lose much time on this account. It was suggested that much benefit would be derived from having a medical college where boys intending to study medicine could enter after having passed one of the preliminary examinations and spend a year, acquiring some knowledge of those scientific subjects that would be of use to them later on; they would then be able on entering at a hospital to study with greater advantage the various medical subjects met with there, and would have more time to devote to attending hospital practice.

Dr. THOMAS exhibited a specimen of Tumour of the Bladder from a patient, aged one year and ten months, who had been under treatment at the Children's Hospital. The history of the case was given for the time it had been under his care, the symptoms being those of retention of urine and cystitis. The ordinary incision for lateral lithotomy was made for the purpose of exploring the bladder, when a hard mass was felt in front and to the left of the median line. The patient was relieved by the operation, and the wound allowed to heal. He was discharged, but returned in a month suffering from a low form of bronchitis, and with a mass protruding through the incision, which had reopened. Further exploration failed to define the tumour sufficiently for surgical interference, and the condition of the patient also made it inadmissible. He died shortly after. The tumour sprang from the base and front of the bladder, and in its growth had enlarged and occupied the base, so that there seemed to be a secondary bladder above it. It was composed of polypoid masses of considerable firmness springing from a common base. A microscopical report by Mr. Jones-Bateman was read, and sections of the tumour were shown. The report stated: "To what class of tumours the specimen should be assigned it is difficult to determine; the base of the tumour might fairly be called a myoma, but in the peripheral portion there is no muscular tissue. The peripheral portion however agrees very nearly with what Sir Henry Thompson calls 'tumours of a transitional type.'"

Mr. HUGH THOMAS showed a man in whom Congenital Absence of Auricle and External Meatus existed. The internal ear, Mr. Thomas thought, was intact. The patient's mother, when he was in utero, was frightened by one of her children being burnt on the side of the head and ear.

Dr. SUCKLING showed a woman suffering from Right Peripheral Facial Paralysis with Reaction of Degeneration, and demonstrated the existence of the reaction of degeneration. The woman, ten weeks previously, had fallen downstairs, after which there was a discharge of blood and watery fluid from the right ear, and her husband noticed the next day that her face was drawn to the left. She was in bed for a fortnight after the injury, and then applied at the Queen's Hospital. Dr. Suckling considered the case to be one of fracture of the base of the skull, the facial nerve in the aqueduct of Fallopius being severely injured. Taste was markedly affected on the right side of the tongue, the patient complaining of the loss. Tartaric acid, alum, sugar, and common salt could not be distinguished by the right side of the tongue.

BATH PATHOLOGICAL AND CLINICAL SOCIETY.

THE second ordinary meeting of the session was held at the Royal United Hospital on Tuesday, December 9th; Mr. S. Craddock, President, in the chair.

Dr. FOX read notes of a case of Tabes Dorsalis simulating in its early stages Myelitis. The patient was a syphilitic woman, aged twenty-five, who had been subjected to much ill-treatment. When in apparent good health she was suddenly seized with paraplegia and pains in the legs, together with girdle pains. The reflexes, both superficial and deep, were absent. No history of alcohol. At this time Dr. Fox was inclined to class the disease as one of myelitis, but subsequently all the reflexes, except patellar, returned, and the power of progression re-established itself, though with ataxic gait. The pupils throughout were contracted, neither responding to accommodation nor light.

Mr. H. W. FREEMAN showed a specimen of a Ruptured Uterus, which occurred during labour in a woman, the mother of eight children, who had been attended by a midwife. Although it was an arm presentation, labour was permitted to proceed for forty-eight hours, help only being sent for when the mischief was done. Mr. Freeman performed abdominal section, when the head of the child was found protruding through a rupture in the anterior wall of the cervix, the neck being tightly grasped by the contracted uterus. No hæmorrhage occurred during the operation. Death took place twelve hours later. At the autopsy no contraction of the pelvis was found. The specimen showed a second rupture in the upper and posterior part of the vagina, which was unexplained.

Mr. R. DAVIS produced a specimen of Cancer of the Pylorus, causing complete obstruction. The patient, a male, aged sixty, came under medical treatment only three months prior to death with symptoms of dyspepsia. The stomach was contracted.

Mr. H. G. TERRY exhibited microscopical sections of a spheroidal-celled Carcinoma of the Breast, undergoing cystic degeneration. The sections showed cysts in early formation. The transformation Mr. Terry considered rare.

Reviews and Notices of Books.

Pyuria, or Pus in the Urine and its Treatment. Comprising the Diagnosis and Treatment of Acute and Chronic Urethritis, Prostatitis, Cystitis, and Pyelitis, with especial reference to their Local Treatment. By Dr. ROBERT ULTZMANN, Professor of Genito-Urinary Diseases in the Vienna Polyclinic. Translated by permission by Dr. WALTER B. PLATT, F.R.C.S. Eng., Demonstrator of Surgery in the University of Maryland, Visiting Surgeon to Bayview Hospital, Baltimore. New York: D. Appleton and Co. 1884.—Dr. Ultzmann's clinic is well known to those who visit the vast Polyclinic of Vienna, and his teaching always attracts a large class of students, who are impressed with the success of his practice. Dr. Platt has done good service to those who are not at home with the German language in translating these clinical lectures on Pyuria. The subject is one of very great importance, and from both a diagnostic and therapeutic point of view the information contained in these lectures is to be welcomed. The point of practice that is chiefly interesting is Dr. Ultzmann's mode of irrigation for chronic inflammation of the prostatic urethra and neck of the bladder. He passes a short silver catheter just beyond the compressor urethræ muscle, and then injects ten or more ounces of a warm mild astringent lotion, which flows into the bladder and is subsequently expelled by the voluntary effort of the patient. In addition to translating the brochure Dr. Platt has added a few valuable suggestions in some foot-notes.

Aids to Public Health. By Dr. J. L. W. THUDICHUM. Baillière, Tindall, and Cox.—In this small volume Dr. Thudichum has succeeded in putting together in the smallest possible compass the general principles which govern the present sanitary laws, and of indicating how such matters as water-supply, sewerage, &c., should be carried out. Something that is useful is said about twenty-seven different and most varying subjects, including vaccination, quarantine, markets, slaughter-houses, smoke abatement, &c., and the whole is contained within fifty pages. The excessive concentration of information which the book exhibits may perhaps turn out to be a drawback, especially if students of

Digitized by Google

public health rest satisfied when they have mastered its contents. The intention of such a work is doubtless to create such an interest in the subject it deals with as will lead the reader to study more exhaustive works.

Diabetes Mellitus. By HARVEY J. PHILPOT. London: Sampson Low, Marston, Searle and Rivington. 1884.—This little book does not lay claim to any originality. Its title page declares it to be a "synopsis of the pathology, physiology, etiology, incipient and progressive symptoms, causes of death, sugar tests, and treatment" of the disease. So far, then, it fulfils its purpose, and the comparatively recent discussion at the Pathological Society upon the morbid anatomy of diabetes has been turned to account in the chapter on pathology, which serves to illustrate how little is really known on this head. The chapter on treatment is furnished with a very ample list of articles of diet which may and may not be allowed to the diabetic, and the subject of urinary tests is more fully detailed than usual in works of this class. On the whole it is a creditable essay, written evidently by one who has carefully studied the subject.

Evolution in History, Language, and Science, pp. 158. London: Crystal Palace, and Simpkin, Marshall, and Co. 1884.—This book consists of four introductory addresses delivered by different lecturers at the Crystal Palace Company's Schools this autumn. Dr. Zerffi pleads for the study of general history; the Rev. W. A. Hales for improvement in the teaching of geography; Mr. Malden indicates the hereditary element working in historical families; Dr. Robinson Thornton gives a short sketch of the English language and its vicissitudes. The title of the book is pretentious, but the lectures, though necessarily somewhat superficial, are marked by some breadth of treatment.

Hints for Invalids and Travellers, with Observations on the Climate of Luxor and Egypt during a Three-years' Residence, 1877-78-79. By T. E. MACLEAN, M.B. Pp. 23. London: Lewis. 1884.—This brochure gives briefly but clearly an account of the various routes by which Upper Egypt may be reached, of the seasons at which it is advisable for invalids to reach and to leave it, of the precautions to be observed by them, especially in the way of clothing and exposure, and of the climate of Luxor as observed by the author during three winters. The information seems carefully drawn up, the advice judicious, and the data respecting the climate are likely to be useful to those who may think of passing the winter in, or sending patients with that view to Upper Egypt.

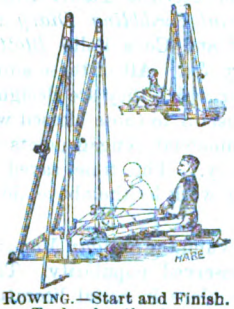
The Most Delightful Voyage in the World, England to the Cape of Good Hope, and South Africa as a Health Resort. By A. WILMOT, pp. 85. London: Richards and Co. 1884.—This is the second edition of a popular account of a voyage to the Cape and of Cape Town, Port Elizabeth, and Natal. To the information given in the first edition has been added a chapter on South Africa as a health resort, its climate and advantages. There appear to be two distinct climates, "one—that of the coast—of an Italian character, where perpetual summer may be said to reign. The other on the high inland tablelands, where the air is remarkably pure and dry, and where the mountain temperature is much lower than on the coast." There is a considerable amount of information given on the subject of the influence of the climate on lung disease, and an account of the spas or mineral springs of South Africa. The appendix gives some useful details respecting the cost of living in, and the social condition, of the Colony, as well as some interesting notes on the South African Gold Fields.

Recent Materia Medica. By F. HARWOOD LESCHER, F.C.S. London: J. and A. Churchill. 1884.—This is a work which is supposed to give information respecting the origin and uses of certain new remedies. The notes are so imperfect that it is difficult to imagine that anyone could derive any information from their perusal.

Leaders in Modern Philanthropy. By WM. GARDEN BLAIKIE, D.D., &c. With fifteen portraits. The Religious Tract Society.—A most commendable book, admirably adapted for use as a present at this benevolent season. Nor is it without interest to the earnest student of creeds and churches, as showing the creed out of which the most stupendous and the most minute philanthropies of the age have arisen; from the philanthropy that abolished slavery to that which overtook Timothy Daly in his too short workhouse bed. By the way, another chapter is wanting on such philanthropists as the late Dr. Anstie.

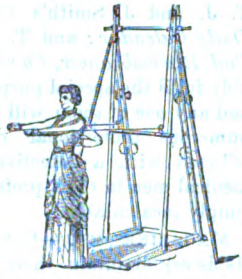
Diaries, Calendars, &c.—As usual at this time of the year we have received many specimens of Diaries and Calendars for next year. Prominent among them are *Letts's Rough Diary, Office Diary*, and *Clerical Tablet Diary*; T. J. and J. Smith's *Commercial Scribbling Diary* and *Daily Calendar*; and T. Pettitt and Co.'s Folio *Blotting Pad Remembrancer, Court Diary*, &c. All of these admirably fulfil the special purposes for which they are designed, and any one of them will prove useful to those blessed with numerous professional or commercial engagements or afflicted with a defective memory. The time saved by medical men in their professional work by the above aids is simply incalculable.

MAGAZINES, ETC.—*Good Words* and the *Sunday Magazine* (Isbister) maintain their well-deserved popularity. They occupy a distinct and honourable place in serial literature, being remarkable for their artistic illustrations as well as for the general merit of their literary articles.—Amongst the tales, grave and gay, which form the staple of *Longman's Magazine*, there are from month to month interspersed articles of a more solid character. Thus the first number for the new year contains a paper by Mr. R. A. Proctor, entitled "Two Sunlike Planets," which forms interesting reading.—The *Leisure Hour*, the *Sunday at Home*, the *Boy's Own Paper*, and the *Girl's Own Paper* (Religious Tract Society) can be mentioned only with commendation, their contents, as a whole, being of a kind which must exert a wholesome influence on the classes of readers to which they are addressed, judiciously combining as they do innocent amusement with instruction, social, scientific, and religious. The first-mentioned periodical gives in the volume for 1884 a series of papers by Mr. J. Cordy Jeaffreson on "Doctors out of Practice," which is of considerable interest to medical men.—Amongst Christmas numbers which have come to hand are those of the *Illustrated London News* (which is, as usual, of excellent quality), the *Christian Million*, and the *Pall Mall Gazette Extra*, which last is well calculated to hold its own beside its larger and more gorgeous competitors for public favour.



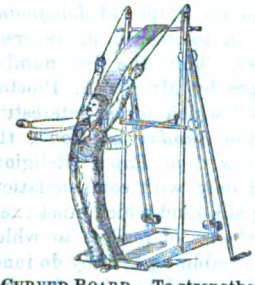
New Inventions.

CHADBORN AND CALDWELL'S PATENT EXCELSIOR HOME GYMNASIUM.

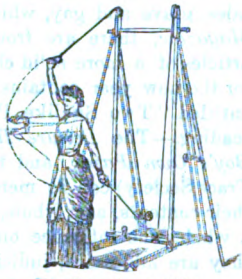


MESSRS. CHADBORN AND CALDWELL have submitted to us one of their Home Gymnasia, which undoubtedly meets most successfully a great and widespread want. The conditions of town life are rendering it more and more important that provision should be made for the suitable exercise of all parts of the frame. Gymnasia have been established in various parts of London, and in all good schools; yet they only partially supply the need that exists, for but a limited number of persons avail themselves of the advantages of these institutions. No doubt a trapeze, which can easily be fixed in nearly every house, will afford an excellent means of obtaining freedom and strength of movement; but the Excelsior Gymnasium has the great advantage that it combines in one a horizontal bar, trapeze,

Digitized by Google



dumb-bells, clubs, spring board, and many other forms of muscular exercise, and that it is adjustable with the greatest ease to children of tender age and to the strongest athletes. The full-sized apparatus occupies about 4 square ft. of floor space, and is 8 ft. high, so that it is easily found room for in most houses. The accompanying cuts give a good idea of its general construction. It is very strongly made and yet light, the bulk of it is in maple, the horizontal bar is hickory, the rowing platform is of ash and the curved board, &c., are of bass wood. By a very simple arrangement the handles fastened to the ropes, which are connected over pulleys with weights, can be fixed at any height. The weights are common dumb-bells, and can be varied according to need from a few ounces to many



ROWING.—Start and Finish. To develop the Arms, Legs, and Back.

Direct Chest Movements. To deepen the Chest and draw the Shoulders back.

CURVED BOARD.—To strengthen the Back, Neck, Abdominal Muscles, and Expand the Chest.

For Curvature of the Spine.

pounds. There are about a hundred varieties of muscular exercise which can be taken with this machine. Not only may the muscles of the arms and legs be developed by it, but the chest be expanded, the spine strengthened, and the muscles of the hands brought into proper use. For young children there is a swing and a spring board which afford amusement, and simple movements that expand the chest. By means of the apparatus lateral curvature of the spine should with certainty be prevented, and no better means of curing this deformity is known to us. From personal experience of its use, we can testify that this gymnasium is thoroughly safe, simple, and efficient. It has the further important advantage of being extremely moderate in price.

CHARING-CROSS HOSPITAL SCHOOL.—The jubilee of this school was recently celebrated, and the annual report read by the Dean, Dr. Bruce, stated that the institution was never more prosperous than at the present time, the entry of new students during the present year having been larger than on any previous occasion. A dramatic performance was afterwards given by the Students' Club at Toole's Theatre, followed by a dinner of the hospital staff, and a ball given by the Dean.

CENTENARIANS.—Mr. James Reilly, of Ballyjamesduff, died last week at the alleged age of 115 years; and Bryan McDonnell, of County Louth, at 106.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN extraordinary meeting of the Council was held on Friday last, when a report (the fourth) of the Committee on the Mode of Election to the Council, and other matters relating to the Charters and Bye-laws of the College, were presented. The two principal objects for which the meeting was convened were—first, the consideration of a motion originating with Mr. Cadge relating to the mode of election of the President; and, second, the recommendations of the Association of Fellows. It was reported that a majority of the committee of six to three had negatived a motion to the effect that the President be elected annually by the Fellows. The minority, however, submitted a resolution in the form of an amendment, that the President should be elected by the Fellows substantially in the way recommended in the scheme prepared by the Association of Fellows. This minority report was signed by Messrs. Holmes, Erichsen, Cadge, and Smith. When put to the vote as an amendment, it was lost by fourteen to five. *For* it were Messrs. Erichsen, Holmes, and Cadge, Sir Joseph Lister and Mr. Allingham; *against*, Sir James Paget, Messrs. Marshall, Forster, Savory, Lund, Wood, Power, Bryant, Hulke, and Croft, Sir William Mac Cormac, Messrs. Lawson, Hill, and Durham. Five members of the Council were absent—namely, Sir Spencer Wells, Messrs. Hutchinson, Heath, Smith, and Jones. The resolution that the President be elected by the Council as heretofore was then carried *nemine contradicente*.

As to the recommendations of the Association of Fellows, some were adopted unaltered, some with verbal alterations, some in part, and some were wholly rejected.

The recommendations of the Association of Fellows which have been accepted by the Council are: (1) Any Fellow who has been a Fellow for ten years or a Member for twenty years shall be eligible to be a member of Council; (2) that any member of Council who may be absent for more than four successive meetings without leave shall *ipso facto* cease to be a member of Council, unless a satisfactory reason for such absence be assigned; (3) the appointment of scrutineers to take the ballot at the election of the Council; (4) the discontinuance of the payment of a fee on election by a member of the Council; (5) the appointment of a treasurer and the auditing of the accounts by a professional auditor; (6) the discontinuance of the payment of a fee on election by members of the Court of Examiners; (7) that Members of the College shall be eligible, as well as Fellows, for the examinerships in anatomy and physiology. (The Council will continue to select the examiners for the Primary Fellowship from among the Fellows); (8) that an annual general meeting of the Fellows and Members shall be convened, at which a report of the Council shall be presented, and that other meetings may be held either by the direction of the President or Council, or on a requisition signed by thirty Fellows or Members; and (9) that the minutes of each meeting of the Council shall be suspended in the hall of the College for the inspection of the Fellows and Members. (The Council has inserted the condition that only the *confirmed* minutes shall be suspended.)

The Council has agreed to make certain modifications as to the nomination of a candidate for a seat in the Council—e.g., three signatures only will be required instead of six. The Council declines to accept the following recommendations:—(1) That not more than one-half of the members of the Court of Examiners shall have seats in the Council; (2) that six members shall retire annually; (3) that "substitute" members shall be abolished; (4) that the Fellows shall elect the President; (5) that the members of the Court of Examiners shall be elected annually, and not hold office for more than five consecutive years; (6) that a new order of Honorary Fellows be instituted; (7) that no alteration shall be made in the constitution or relation of the College without the consent of the Fellows and Members convened to discuss such alteration.

At the same meeting of the Council Mr. Marshall's proposal to reduce the fee for the Membership when obtained through the combined examination from twenty guineas to fifteen was adopted. Sir James Paget gave notice that at the next meeting of the Council he would move that the Council take measures for placing in the College an appropriate memorial of the late Sir Erasmus Wilson.

THE LANCET.

LONDON: SATURDAY, DECEMBER 27, 1884.

THE ANNUS MEDICUS 1884.

THE last number of THE LANCET of another year brings us again to the duty of "talking with our past hours." This is not always a pleasant exercise, but it may at least be made a profitable one. We generally show pity on our readers by a short preface, and by going at once to the principal items of our summary, and on this occasion we shall make no departure from this rule. Medical Science and Practice, with the fundamental sciences of Anatomy and Physiology, need no introduction to our readers. They are familiar as household words, save in their latest advances and bearings, which it is the chief object of our Summary to elucidate. Year after year gives fresh illustrations of the extensive and professional bearing of Medicine, in its largest sense, on the welfare of individuals and communities. What misery and what money France and Italy might have been saved this year by better methods of protecting and preserving the public health! The day will come when States will think more of averting epidemics and developing the health of citizens than of either coarse or curious systems of Representation, and when they will judge differently their greatest benefactors. This question is vital, not only for old countries like our own, but for new ones. Our columns have shown how unhealthy are the conditions of life in New York, giving a mortality of 34·01, against an urban mortality in England of 20·3. Meantime, Medicine is to be cultivated by its disciples silently and diligently for its own sake, for the people's sake, who need its guidance, and for the sake of Him whose agents we are, "who healeth our diseases."

Anatomy and Physiology.

The departments of Anatomy and Physiology have been enriched by numerous new and valuable works. Amongst these may be mentioned: YEO'S Manual of Physiology; PREYER'S interesting and original Physiologie der Embryo; VOGT'S Anatomie comparée; WALDEYER'S Anatomie; CHARLES'S Physiological and Practical Chemistry; HART'S Atlas of Female Pelvic Anatomy; RUDINGER'S Anatomie des Prostate; PURSER'S Manual of Histology; FOL'S Lehrbuch der Vergleichenden Mikroskopischen Anatomie; and PARKER'S Hunterian Lectures on Mammalian Descent, written in a semi-popular but truly original and extremely quaint style. Professor FOSTER and Mr. MORRANT BAKER have published new editions of their works on Physiology, and Mr. POWER an elementary text-book on the same subject. WERNICH and HIRSCH have commenced the issue of a valuable Biographical Lexicon of conspicuous names in medicine; the first volume includes an account of well-known physicians and surgeons in all countries as far as CHAVASSE, with an enumeration of their works. Quite recently an excellent translation by Dr. STIRLING of LANDOIS'S Physiology has appeared. Numerous memoirs have been published in PFLÜGER'S *Archiv*, the most important being those on the Disturbance of Vision after Injury of the Cerebral Cortex, by LOEB; the researches made by COHNSTEIN and ZUNTZ on the Blood Circulation and Respiration of the Mammalian Fœtus; the essays of WORM MÜLLER on the Excretion of Sugar and the Estimation of the Sugar excreted by the Kidneys in Man, and of KARL BOHLAND on the Quantitative Determination of Nitrogen in the Urine; and the interesting essay by GOLTZ on the Functions of the Brain. The School of Physiology at Cambridge is doing good work and attracting a yearly increasing number of students. When will Oxford follow the initiation of the younger university and bestir herself? FOSTER'S *Journal of Physiology* contains some excellent memoirs, the chief being those of BURDON SANDERSON and PAGE on the Electrical Phenomena of the Excitatory Process in the Heart of the Frog and the Tortoise, in which a method of obtaining photographic records of the phenomena of plant and animal electricity is detailed; KLEIN'S essay on the Swine Plague; and the essay of LANGLEY and SHERRINGTON on Secondary Degeneration of Nerve Tracts following Removal of the Cortex of the Cerebrum in the Dog. In Professor HUMPHRY'S *Journal of Anatomy*, Dr. BARRETT attacks the oft-disputed question of the Cause of the First Sound of the Heart, and arrives at the conclusion that it is exclusively due to the vibration of the auriculo-ventricular valves, and that muscular contraction has nothing to do with it; AINSLIE HOLLIS gives a good account of the Histology of the Central Grey Substance of the Spinal Cord, Medulla Oblongata, and Pons Varolii; and Dr. YOUNAN carefully describes the Histology of the Vitreous Humour.

Pathology.

Pathological science has lost this year one of its most brilliant and most able expounders. The death of JULIUS COHNHEIM in August not merely deprived Leipsic of a professor, but removed an acute thinker and laborious investigator in Pathology, which owes very much to the ideas he promulgated and the facts he discovered. One of COHNHEIM'S pupils and fellow-workers, Dr. C. S. ROY, was elected to the newly founded chair of Pathology at the University of Cambridge, and Mr. VICTOR HORSLEY, of University College, London, was appointed Professor to the Brown Institution in the place of Dr. ROY. The great subject of the year has been the cholera, and the interest taken in recent attempts to determine its true nature has been increased by the spread of the disease to Europe. In the spring Dr. KOCH and his two colleagues returned from India, having accomplished their mission in a manner which received adequate acknowledgment at the hands of the German Government and the profession in all countries. In July Dr. KOCH expounded his views upon the subject at a special conference, and staunchly maintained that the comma-shaped bacillus was the specific cholera organism. The leaders of the profession in Berlin, including VIRCHOW and HIRSCH, appeared convinced by the arguments adduced by KOCH. But this discovery has not been allowed to pass unchallenged. Dr. T. LEWIS in our columns pointed out the existence of similar organisms in the buccal secretion, and Drs. FINKLER and PRIOR of Bonn published an account of their researches into cholera nostras, in which they aver they have also detected the comma bacillus. To these and other objectors

Digitized by Google

KOCH replied, still maintaining that his position was unshaken. The successful inoculation of cholera by direct intra-duodenal injection of the bacilli by NICATI and RIETSCH at Marseilles supplied a defect in KOCH'S argument for which he has been much assailed; and further testimony in support of this doctrine has been furnished by Dr. VAN ERMENGEN in Brussels and M. CORNIL in Paris. But the year passes without a determinate result, or anything approaching to unanimity on this important question. In this country Professor RAY LANKESTER has written to the lay press to discredit KOCH'S labours; and Dr. KLEIN, shortly after the news of the discovery became known, stated objections to it in the columns of *Nature*. The last-named gentleman was despatched with Dr. H. GIBBES by the English Government to India, to pursue a scientific inquiry similar to that undertaken by the German Commission in the previous year. So far as is yet known the English Commission have arrived at results which do not bear out the conclusions stated by KOCH. It is quite plain, then, that the pathology of cholera is still an open question, and it may remain for many years the battle-ground for pathologists which it has so long been. The next most important subject of the year has been the account furnished by Professor PASTEUR of his researches into the nature of the virus of rabies, and its mode of action on the body, together with his discovery of protective inoculation, which may not only greatly diminish the spread of the disease among dogs, but may possibly be found of invaluable service in protecting an individual from the development of hydrophobia; for M. PASTEUR thinks that the long period of incubation in this disease might afford time for a protective inoculation to take effect. The interest taken in the tubercle bacillus has suffered no diminution, and the publication of KOCH'S monograph on this subject, in the second volume of the Reports of the German Imperial Board of Health, has done much to maintain this interest. The same publication contained several important memoirs giving accounts of researches in that department of pathology which is most advancing—viz., the specific infective diseases; for instance, that on Diphtheria, by Dr. LÖFFLER, and on Typhoid Fever, by Dr. GAFFKY. FRIEDLAENDER'S discovery of a micrococcus in acute fibrinous pneumonia has been confirmed by other observers, and has been put to account by recent writers upon the etiology of a disease which in many respects bears a strong resemblance to a specific fever. The observation made last year by Professor KOCHER of Berne, that individuals who had undergone extirpation of the thyroid body became the subjects of a special cachexia, which bears a striking resemblance to myxœdema in its clinical features, has led to an experimental inquiry, the results of which have been recently expounded by Professor HORSLEY. The prosecution of this work may throw much light, not merely upon myxœdema but on the function of the thyroid and upon cretinism. Many interesting observations upon rickets in animals have been made by Mr. J. B. SUTTON, who has also pursued an investigation into ovarian disease in the lower animals which he detailed lately at the Pathological Society. Mention must also be made of the brilliant Bradshawe Lecture by Mr. SAVORY upon Cancer, which was as notable for its philosophical spirit as for the eloquent language in which it was couched. The year has not been signalised by any very notable additions to pathological literature, but the rapidity with which new issues of well-known treatises are called for is satisfactory proof of the growing interest taken in the subject and of its place in medical study. The laboratory opened at the Health Exhibition on the pattern of the Berlin institution is, we trust, the foreshadowing of a permanent foundation which will enable pathological research to be prosecuted in this country with facilities equal to those enjoyed on the Continent.

Therapeutics.

The past year has proved an eventful one for Practical Therapeutics. Recent experience seems to assign to cocaine the highest place in the class of local anæsthetics, though it is quite possible that future observations may not fully bear out all the flattering testimonies advanced in favour of the drug. The promise of the future lies possibly not so much in what cocaine itself may accomplish, as in the expectations which its properties seem to open out to us. If cocaine can do so much, are there not other alkaloids capable of effecting more? Meanwhile, we must hope for the further development of the resources of cocaine. Cases of sciatica may possibly find their cure in a few injections into the neighbourhood of the nerve of a weak solution of the muriate of cocaine. This method has already been tried by Dr. MURRELL for supra-orbital neuralgia, for which malady it would appear not to be suitable, as the pain of injection is so great. Nevertheless, a few minims of a solution of hydrochlorate of cocaine in oil of cloves, rubbed in with the finger, seem to have afforded instant relief. The value of cocaine in ophthalmic, aural, laryngeal, nasal, and oral surgery seems already to have been placed on a sure basis. Cocaine has occupied so much of our recent space that there is no need to dilate further on its properties in this place. Whilst the introduction of cocaine is the one grand triumph of the year, we must, nevertheless, not lose sight of the steady progress in other directions. Osmic acid, used in the form of subcutaneous injection, appears to have proved of much benefit in the treatment of some cases of obstinate neuralgia. Menthol as an external application has achieved success in a similar class of cases. Antipyrin and kairin have attracted a large share of attention as antipyretic agents, and the new drug thallin may be mentioned here. Various new oleates have been introduced into therapeutics by Dr. SHOEMAKER (THE LANCET, *ante*, p. 123). An infusion of the seeds of jequirity has been employed in cases of unhealthy, ulcerating, and granulating conditions of skin. The hypodermic injection of corrosive sublimate and other preparations of mercury has been suggested for the treatment of syphilis, but the method has not as yet been received with much favour. The comparative action of carbolic acid, convallaria, and atropia on the heart has been well studied in tortoises and frogs by Dr. BEYER, in Washington, U.S. Freezing the skin by means of chloride of methyl along the course of the sciatic nerve has been practised with success in cases of sciatica by M. DEBOVE. Whooping-cough has been treated by M. MONCORVO with a 1 per cent. solution of resorcin applied frequently to the pharynx and larynx by means of a brush mounted on a long handle. The value of the imbibition of large quantities of distilled water in the

Digitized by Google

treatment of calculous disorders has received fresh attention; it is now some years since Dr. MURRAY advocated the continued use of soft water as a means of disintegrating small renal calculi. In surgical therapeutics the extension of the use of corrosive sublimate as an antiseptic dressing for wounds has been largely due to its advocacy by Sir JOSEPH LISTER, at a meeting of the Woolwich Military Medical Society in the early part of the year. The antiseptic treatment of wounds by dry and infrequent dressings was the subject of an excellent clinical lecture delivered by Dr. F. J. SHEPHERD at the Montreal General Hospital. In the night sweats of phthisis the active principle of the white agaric—agaricine—has been employed by M. SEIFERT, of Wurzburg, in the form of pills containing five milligrammes of the alkaloid. The treatment of maniacal delirium by means of the cold douche so favourably spoken of by Dr. BROADBENT has been tried with success by Dr. T. BARLOW. Dysentery in some of its forms is still as obstinate as ever to treatment, so that we welcome such attempts in the region of Practical Therapeutics as those of Dr. STEPHEN MACKENZIE on the voluminous injection of solution of nitrate of silver, and of Dr. J. EWART on the value of large doses of ipecacuanha given night and morning. The discussion and papers on the Cold Bath Treatment of Typhoid Fever by Drs. BRISTOWE, BROADBENT, CAYLEY, and COUPLAND was one of the most interesting features of the work at the Medical Society. As a scientific aspect to this practical treatment we may mention the researches of Dr. SASSETZKY on the use of cold in the abatement of fever (THE LANCET, vol. i., 1884, p. 14). Dr. HARE'S protest against the neglect of old-fashioned remedies such as leeches and venesection deserves to be mentioned for the simple reason that there is too much fashion in therapeutics. No doubt fashion may be merely an equivalent for giving a remedy a trial, and a failure of a remedy would necessarily lead to its falling out of use; so that in the onward march of therapeutics change of fashion, in a certain sense, must be regarded as an advantage. It cannot be questioned that we ought to be more thoroughly acquainted with the mode of action of our more familiar remedies than is at present the case. The scientific contribution of Dr. MATTHEW HAY on the mode of action of saline cathartics must be accorded a very high place in the list of new work which has attracted notice during the past year. Amongst the matters which call for consideration we may note the attempt to get rid of some of the evils which surround the present state of legislation in regard to patent medicines. This is a subject which we hope will in the coming year undergo reform. We may conclude this brief summary by praising the continued efforts of the pharmacists to present the profession with preparations from which all the disagreeable properties are hidden by means of elegant devices. We refer to the various compressed tablets, solid liniments, new forms of coated pills, and the like.

The Progress of Surgery.

For several years we have been accustomed to commence our review of the progress of Surgery during the previous twelve months by a notice of the development of the various modes of dressing wounds, and particularly the antiseptic treatment. Each year has witnessed some progress and change, and 1884 is no exception in this particular. The use of iodoform as a dressing for recent wounds has certainly become more general, and has been attended with excellent results. But attention has been chiefly directed to the employment of corrosive sublimate as a surgical dressing, and on the Continent especially this agent is very widely used, with most satisfactory results. Sir JOSEPH LISTER has dealt with the question in his usually careful and exhaustive manner, and, in a paper which appeared in our columns, has clearly pointed out the merits and demerits of corrosive sublimate, and how the latter may be counteracted. The cheapness of this material, and the ease with which it may be used, together with its valuable antiseptic properties, favour the likelihood of its being generally adopted as a dressing for wounds. The wood-wool dressing, which has been much used and highly spoken of in Germany, has not found so much approval here, being cumbrous and practically inferior to other materials. Dry dressing, in the form of sheets of pure absorbent cotton-wool, is very popular with many surgeons, and is more widely employed than formerly. Early in the year a very important debate was held at Woolwich on the adaptability of antiseptic surgery to the first dressings in military practice, and a very general expression of opinion in favour of the use of antiseptics—especially iodoform and corrosive sublimate—on the field of battle was elicited. Turning from the question of the treatment of wounds to the consideration of the extensions of the field of operative surgery effected or made known during the year, we find they are neither few nor unimportant. Quite recently, Mr. RICKMAN GODLEE has excised a gliomatous tumour from the cerebrum of a man, and has demonstrated the possibility of the procedure. This case is not yet completed, nor have we sufficient data to enable us to estimate the value of the operation, for at present we are in ignorance how far the removal of a cerebral tumour will be attended with relief to paralytic or other phenomena caused by it, and, what the probability of local recurrence may be. The case is, however, a triumph for the precision of medical diagnosis, and an evidence of the great advance of operative surgery during the present generation. The surgical treatment of gangrene of the lung and of basic pulmonary cavities has also attracted much attention, and Dr. CAYLEY and Mr. PEARCE GOULD have recorded two cases of gangrene treated by incision into the lung and drainage, which afford much encouragement to the further prosecution of this branch of surgery. Renal surgery has made steady advance, but there is still a wide difference of opinion as to whether the abdominal or the lumbar operation is the better when nephrectomy is necessary. Sir HENRY THOMPSON'S lectures at the College of Surgeons testify to the progress made in the exploration and removal of vesical tumours. Excision of the intestine has been practised in a few instances, and among the successful ones we may refer to one recorded in our columns by Dr. MACDONALD. The radical cure of hernia by operation and suture of the sac, or of the ring or of both, has gained in general favour, and is now largely practised, with results which certainly warrant the procedure. The surgery of the osseous system has established for itself a proud position. At the meeting of the International Medical Congress, at Copenhagen, Dr. MACEWEN read a valuable paper on Osteotomy, show-

Digitized by Google

ing the great extent to which the operation has been practised, and the remarkable immunity from accident that attends it. In our columns have been recorded two cases of wound of the popliteal artery in connexion with division of the lower end of the femur, one of which ended fatally. Mr. BARKER has suggested the treatment of hallux valgus, when severe, by resection of a portion of the metatarsal bone of the great toe; and Dr. OGSTON read a paper at the Medical Society on the Treatment of Flat-foot by Resection of the Astragalo-scaphoid Joint. Mr. TREVES has introduced the plan of opening psoas abscess in the loin instead of at the groin, not only with a view to better drainage, but also to removing sequestra or to treating the disease of the spine directly when it admits of it. At present the latter object has not proved attainable in the majority of cases. Early in the year the discussion on catheter fever raged fast and furious, and was useful in directing attention to a subject of much importance that has been treated with too much neglect. Far from complete as is this review, it shows that the advance of surgery during the year has been distinct, and affords evidence of the enthusiasm and devotion with which it is practised.

Obstetrics and Gynæcology.

Much activity has been shown in the department of Obstetric Medicine. The papers read before the Obstetrical Society have been numerous and important, and we would refer to Dr. GRAILY HEWITT'S paper on the Vomiting of Pregnancy; Dr. E. S. TAIT on Puerperal Temperatures; Dr. MATTHEWS DUNCAN on Fœtal Revolution; DUNCAN and HURRY on Retroflexion of the Fœtus; and HOPKINS WALTERS on Post-partum Avulsion of the Uterus. Before the Obstetrical Society of Edinburgh Dr. BARBOUR read a valuable paper on the Anatomical Relations of the Uterus during the Third Stage of Labour and the First Days of the Puerperium. The papers of Drs. GRAILY HEWITT and HEHMAN on Anteflexion and Displacements of the Uterus, which appeared in our columns, deserve careful perusal. They show the two sides of this much-debated subject, and go far to set it at rest. Several works of great value have been published in this department, among which we would mention HART'S Atlas, DORAN'S Tumours of the Ovary, and TAIT'S Diseases of the Ovaries.

Ophthalmology.

Ophthalmology has received several important additions. Mr. HARTRIDGE has written an excellent little work on Refraction, which should be in the hands of all those who are engaged in the study of diseases of the eye. Dr. SWANZY of Dublin has published a handy and very useful compendium of the Diseases of the Eye in general, which we have very recently favourably reviewed in these columns. The Ophthalmological Society is prosperous, and has published its fourth volume, which contains many interesting memoirs. Abroad, Messrs. WECKER and LANDOLT have issued another part of their large Traité d'Ophthalmologie. SCHMIDT-RIMPLER has added one more to the numerous German Treatises on Augenheilkunde und Ophthalmoscopie. An effort has been made by Dr. MCKEOWN of Belfast to diffuse amongst the laity some knowledge of the danger, and the necessity for prompt and appropriate treatment if blindness is to be averted, of the purulent ophthalmia of infants, and it is much to be hoped, in the interests of humanity, that this effort will prove successful. By far the most interesting event of the year in this subject is the introduction into ophthalmic practice of two remedies—jequirity and cocaine. The former, the value of which has been strongly advocated by M. DE WECKER, is the small round or oval red seed with a black spot which is the product of the abrus precatorius. It has been largely employed in France and America, and to a small extent in this country and in Germany, as an agent for the cure of trachoma and superficial keratitis. The infusion, which is found to contain a base of an irritant character named jequiritine, and to be a fluid in which certain forms of bacteria propagate with great rapidity, to both of which its active powers have been attributed, sets up, when applied to the conjunctiva, very sharp inflammation. The result of the inflammation appears to be the contraction, and ultimately the obliteration, of the bloodvessels of the conjunctiva, leading to the disappearance of the granulations on the inner surface of the lid and the recovery of the transparency of the cornea. Some experience appears, however, to be necessary in the selection of appropriate cases, since bad results have been occasionally reported as occurring from its use. The value of cocaine is less open to objection, and there can be no doubt that a remedy of very great value has been added by Dr. KOLLER to the list of remedial agents applicable to ophthalmic surgery. Its effect, when applied in solutions varying from 4 to 20 per cent., is to produce local anæsthesia. It should be applied four or five times at intervals of about five minutes, its absorption being promoted by gentle friction upon the lids. It produces remarkable pallor, and such complete loss of sensibility that puncture and section of the cornea are scarcely felt. It is invaluable in cases of impaction of foreign bodies into the cornea, which are commonly attended with intense suffering, and such spasm of the lids as renders their extraction in many instances extremely difficult even in skilled hands; but whether it produces anæsthesia of the deeper tissues, as of the iris, still remains questionable. In the meanwhile the rarity and expense of the drug, at first considerable, are rapidly diminishing.

The Royal College of Physicians.

In the history of an institution that can boast of an existence ranging over three centuries the record of a single year does not leave much mark, unless in the course of that period some notable changes have been made affecting the constitution or the privileges of the body. The past year has witnessed such a change, and will be remembered by some with regret, by others with rejoicing, as the time when the College of Physicians voluntarily abandoned its right to confer a complete double licence, and, in conjunction with the sister College, established an examining board for England. The wisdom of the step has been questioned, but it was doubtless hastened by the renewed but once more abortive attempt at legislation which would have considerably affected the interests of both the Colleges, for the withdrawal of the Medical Act Amendment Bill was speedily followed by the promulgation of this combination scheme, which in due course was sanctioned by the General Medical Council. It is not possible to forecast the result of the new

Digitized by Google

departure; it ought not only to extend the curriculum of the medical student, but should do much towards enforcing a more practical system upon the medical schools. The Conjoint Committee lost no time in preparing the details of the scheme, which is to be put into force at once, for under certain conditions it will have a retrospective effect. The College, of course, retains the right of conferring its Membership and Fellowship as hitherto. In regard to the last named-distinction, this year will be memorable for an event almost unprecedented in the annals of the College. The Fellows are elected by the Comitia, on the nomination of the Council, from among the list of Members. This year the nomination list was so unsatisfactory to many of the non-official Fellows, on account of names omitted, as well as of some included in the list, that this was referred to the Council. Legal opinion was taken, with the result that the day of election being overpassed no new Fellows were chosen this year at all. The Nomenclature Committee of the College completed its labours during the year, but the publication of the volume is still to come. The Pharmacopœia Committee has also made progress with its work of determining what new remedies shall receive "official" sanction and what old ones shall be disregarded. An attempt to stimulate the College to revert to its old prerogative of setting its hallmark upon drugs was made by the late Dr. MAHOMED, but failed to meet the support for which he so urgently pleaded. Amongst the questions debated at the College, the one bearing on the title of doctor excited some interest, but no conclusion was arrived at, and for the nonce at least there remains but one narrow portal whereby a London student can obtain the coveted degree in London. By the death of Dr. BARCLAY the College lost its treasurer, after a brief tenure of office, and he was succeeded by Dr. DYCE DUCKWORTH. A resolution appointing two Vice-Presidents was passed, and Sir W. JENNER was again chosen President. The Harveian Oration, delivered this year in October, was given by Dr. RUSSELL REYNOLDS; it was an eloquent panegyric. The Bradshawe lecturer, Dr. PHILIPSON (of Newcastle), took for his subject Diseases of the Lymphatic System. Dr. CLIFFORD ALLBUTT delivered the Gabstonian Lectures, on Visceral Neuroses; Dr. HUGHLING JACKSON the Croonian, on the Evolution and Dissolution of the Nervous System; and Dr. ANDREW the Lumleian, on the Etiology of Phthisis.

Royal College of Surgeons.

The Royal College of Surgeons of England has, during the year, attracted an unusual amount of notice, partly in consequence of certain agitations for domestic reform, and partly as the result of some important changes in what may be called the foreign policy of the Council. In order to follow the current of the present agitation for reform it is necessary to remember that on July 12th, 1883, a committee of the Council was appointed to consider and report on the mode of election to the Council and other matters relating to the Charters and Bye-laws of the College. The first report of this committee was presented on Nov. 8th, 1883, when it was recommended that Fellows should, in future, be allowed to vote at the election of the Council either in person or by voting-paper. This recommendation was adopted, and thereby compulsory personal voting was doomed. On Jan. 10th, 1884, the committee presented its second report, in which certain alterations were recommended to be made in the Charters of the College. The principal alterations proposed were: the increasing of the amount of the yearly value of the property in lands or rents to be held by the College from £2,000 to £10,000; the determining of the conditions of admission to the Fellowship by a Resolution of the Council instead of by Bye-law, as heretofore; the fixing the fee for the Fellowship by Bye-law instead of by Charter; and the abolition of the fee payable by Members of twenty years' standing who should be elected to the Fellowship. At the same meeting of the Council it was resolved, on the motion of Mr. ERICHSEN, seconded by Mr. HOLMES, to refer to the consideration of the Committee the 14th Section of the Charter of the 7th Victoria, relating to "Substitute" Members of the Council. On the 14th of the following month the Committee presented its third report, in which it was recommended that it was inexpedient to make any alteration in the said section. This report, like its predecessors, was adopted by the Council. It was then resolved, on the motion of Mr. ERICHSEN, seconded by Mr. CADGE, that the President should, in accordance with Section XVIII. of the bye-laws, convene a meeting of the Fellows and Members of the College for the following purposes:—"To report to the Fellows and Members the alterations in the Charters proposed to be made by the Council, and to receive from them any suggestions or recommendations with respect to these or any other alterations in the Charters which they may have to offer for the consideration of the Council." The general meeting of Fellows and Members was held on March 24th. The alterations proposed by the Council, having been read and discussed *seriatim*, were ultimately approved by a majority of those present. Thereupon, on the invitation of the President and in accordance with one of the purposes for which the meeting was convened, many suggestions and recommendations with respect to other alterations in the Charters were made and carried. Among these were (1) that the Fellows and Members should be invested with a larger share in the management of the College; (2) that there should be an annual meeting of the Fellows and Members, at which the annual report of the Council should be presented; (3) that the President should be elected by the Fellows, and not exclusively by the Council; and (4) that no alteration should be made in the constitution or relations of the College without the consent of the Fellows and Members convened to discuss such alteration. Another recommendation was also made, to the effect that the College should amalgamate with the College of Physicians to examine conjointly and confer degrees in medicine and surgery. The recommendations and suggestions made by the Fellows and Members at the general meeting were taken into consideration by the Council on May 8th, and were all rejected, except one that did not involve any alteration in the Charters—viz., that an annual meeting of the Fellows and Members be called at which a report from the Council shall be presented. This action of the Council was speedily followed by a result natural and inevitable. Many of the *Members* of the College had already formed themselves into an Association for the purpose of obtaining a larger share in the management of the College; and now the rejection by the Council of the recom-

Digitized by Google

mendations adopted at the general meeting was promptly followed by the formation, at the instigation of Mr. PAUL SWAIN of Plymouth, of an Association of Fellows, to endeavour to secure a reconsideration of the rejected recommendations under more favourable conditions, and to promote reform generally in the College. The Association, which in two or three weeks numbered more than two hundred Fellows, held its first meeting in the rooms of the Medical Society of London on June 12th. At this inaugural meeting, under the presidency of Mr. GEORGE POLLOCK, three of the recommendations originally carried at the general meeting of Fellows and Members were re-affirmed—viz., that the Fellows and Members should be invested with a larger share in the management of the College, that no alteration should be made in the constitution of the College without the consent of the Fellows and Members convened to discuss such alteration, and that the report of the Council presented at the annual meeting should be discussed, and if approved, adopted. Lastly, a committee was appointed to take such steps as might seem desirable to further the objects of the Association. The succeeding events are so recent that they will be within the easy recollection of our readers. It will, therefore, be enough to mention that the committee appointed by the Association of Fellows drew up a scheme of reform, which was presented at a general meeting of the Association held on November 8th. A report of that meeting, including the various recommendations that were finally adopted and ordered to be submitted to the Council of the College, appeared in our columns on November 15th (p. 887). The Council considered the recommendations at an extraordinary meeting held on the 19th instant. An account of this meeting, at which the fourth report of the committee of the Council of the mode of election, &c., was presented, appears in the present issue, and shows to what extent the majority of the Council are in sympathy with the main body of the Fellows and Members.

The other matter of chief interest in the history of the College during the year is the combination into which the College has entered with the College of Physicians for the purpose of holding a complete conjoint examination in Medicine, Surgery, and Midwifery. The combination scheme was approved by the General Medical Council on Oct. 9th, and on Dec. 11th the Council of the College appointed its share of Examiners under the scheme (*see* THE LANCET, Dec. 13th, p. 1074).

Of the matters of more personal interest, it may be mentioned that Mr. FLOWER, F.R.S., has resigned the office of Curator of the Museum of the College, the duties of which he had for twenty-two years discharged with "admirable care, judgment, and zeal." Mr. FLOWER, who has been appointed by the trustees of the British Museum superintendent of the Natural History department at South Kensington, has been succeeded at the College by Mr. CHARLES STEWART. At the election of Council in July Mr. THOMAS SMITH was re-elected, and Messrs. LAWSON, DURHAM, HILL, and ALLINGHAM were elected. At a meeting of Council held on Aug. 5th the Honorary Gold Medal of the College was awarded to Sir ERASMUS WILSON. Though Sir ERASMUS was able to receive and appreciate the honour conferred upon him by the Council, he died three days later, leaving the College his residuary legatee, by which, it is expected, the College will eventually receive about £200,000.

Army, Navy, and Indian Medical Services.

Some important modifications have been introduced during the past year into the medical service of the army. The medical officers and the Army Hospital Corps have been united under the title of the Army Medical Staff Corps; the examination of surgeons before promotion has been restored, and that of surgeons-major introduced. A definite period has been fixed for retirement from the professorships in the Army Medical School at Netley; the appointment of a military commandant of the Royal Victoria Hospital, Netley, has been abolished; and some new regulations have been issued by the Horse Guards relating to the organisation of general hospitals at the base of operations in time of war. In the Navy an important change has been made in the system of nursing, by the introduction of trained lady nurses into the hospitals, and the organisation of a trained sick-berth staff to replace the untrained men nurses hitherto employed, both in the naval hospitals and on board ship. In the Indian medical service the absurd term of "unemployed pay" has been replaced by that of "grade pay" and the issue of the rates comprehended under that head has been restricted to officers who are in receipt of staff salary in addition to their pay; all surgeons not holding executive charges are in future to be placed on the same footing as those of the army medical staff similarly situated. We regret that no change has been made with regard to "officiating pay," nor in the regulations by which medical officers are required to pay their way to all appointments in which they draw higher pay without any reference to these having been made in the interests of the service or at the request and for the convenience of the officer.

The General Medical Council.

THE General Medical Council has held two meetings this year, the first one extending from March 24th to April 2nd inclusive; the second from Oct. 7th to the 16th. It would be a moderate estimate of the cost of these two meetings to say that they took more than £2000 out of the coffers of the Medical Council—that fund the balance of which the Government, in its Bill, proposed to use for "the good of the profession." Farewell now to the Bill and to the good of the profession. When the Council met in March last the President, with much earnestness, expressed his hope that before their next meeting medical legislation would be completed, and his belief that only by the passing of some such Bill as was then before Parliament could the questions be settled, and an agitated profession calmed. There was no question of moment to discuss, he said, nothing to occupy them more than two or three days. They sat eight days with little to show for it, but a few decisions on cases of irregular or infamous conduct, and the sanction of the Scotch Conjoint Scheme. At the October meeting the Council was in good spirits at the defeat of the Medical Bill and the demonstrated incapacity of Parliament, as at present constituted and conducted, to deal intelligently and firmly with legislation affecting the medical profession and through it, the public. They sat nine days, doing more than nothing. Sir HENRY ACLAND dealt lightly with the failure of legislation for which he had so

Digitized by Google

hoped, and which, in March, he thought so indispensable. The Council did what it always does when it has nothing else to do—it spent whole days in tampering with its regulations on preliminary education, and in giving constant trouble to students and examining bodies. It is not two years since some of its last recommendations on preliminary education came into operation. As it had sanctioned a Scotch Conjoint Scheme in March, it with equal glibness, sanctioned an English Conjoint Scheme in October. It relegated various questions to the Branch Councils, on which they will spend a great deal of money and time, and which will all have to be reconsidered at further cost of money and time by the General Council. We should have said that at the beginning of the meeting Sir HENRY ACLAND was re-elected to the chair for the third time, not altogether unworthily. True, he lacks firmness and force. He is helpless in the hands of the representatives of half a score of corporations, which in the interest of the profession should be reduced to half a dozen. But that is partly the fault of a strong Government who did not use his strong words of March to press their Bill on the House of Commons.

The Medical Societies.

Of the various Medical Societies, the Clinical is still the most popular, and the renewed vigour of the Medical Society of London has not diminished. The Pathological Society is the one which needs most reform, and what we urged last year holds still good at the end of this. A stop should be put to the reading of papers on subjects which have been well nigh threshed out. It would be well if separate arrangements were made whereby specimens might be exhibited without publication in the Transactions. Some sort of understanding of this kind would no doubt meet the necessities of the case. Or it would be possible to increase the utility, powers, and work of the Morbid Growths Committee if members were allowed, on notification to the secretary, to have specimens submitted direct to the committee before being read at the meeting of the Society. The subjects which have attracted most attention at the various Societies have received so much comment and mention at our hands in various ways and on several occasions, that it is superfluous to recall them in the present summary. It will, therefore, suffice to record the chief landmarks in the year's progress. At the Clinical Society the *chef-d'œuvre* has unquestionably been the series of meetings devoted to the discussion of Charcot's Disease. Myxœdema and Spina Bifida still form the subjects of patient investigation by the committees which were appointed to inquire into these matters last year. Cholera was the most important attraction which the Epidemiological Society gave its members; the names of Sir JOSEPH FAYRER, Sir W. G. HUNTER, Surgeon-General LONGMORE, Dr. THORNE THORNE, and Mr. SHIRLEY MURPHY must be mentioned in this connexion. The treatment of Enteric Fever by cold was the most interesting of all the subjects which the Medical Society of London dealt with; and the debate on Catheter Fever may be described as the most exciting and brilliant, though its practical results can hardly be said to have been enhanced by the debate. The question was one of pathology, and we may sum up the debate by saying that the state of knowledge remains pretty much where it was prior to Sir ANDREW CLARK'S awakening of the subject. As matters brought before the Royal Medical and Chirurgical Society, we have to chronicle the discovery of the Nervi Nervorum by Mr. VICTOR HORSLEY; the contributions to Pulmonary Surgery by Dr. CAYLEY, Dr. K. FOWLER, Mr. PEARCE GOULD, and Mr. R. J. GODLEE, must be regarded as of considerable practical importance. The painstaking researches of Dr. PERCY KIDD on the Tubercular Bacillus and of Dr. F. C. CHAMPNEYS on Cervical Emphysema must not be allowed to pass without a word. The work done at the other London and provincial medical societies has been characterised for the most part by earnestne s and thoroughness; new facts have been added to our science, thereby swelling its general bulk, and it is to this accumulation of the results of observation that we trust for the steady development, and even progress, of medicine, in the widest application of the term.

The International Medical Congress at Copenhagen.

The International Medical Congress at Copenhagen well deserves a separate notice. The Congress was the eighth of the series of Congresses so well designed to advance medical science, and with it the deepest welfare of nations, as well as to improve the international sentiment. The number of members was large, larger even than in London, amounting to about 1700. It will surprise no one who has visited Denmark and the neighbouring countries to learn that Scandinavian hospitality was unbounded. From the King, who was at once the patron and the host of the Congress, and the Municipality, who also entertained the members, to the profession and the people of the country, one long hearty note of welcome and interest was elicited from Sunday, the day of the formal opening—the Danes are known to have no difficulty in doing both work and worship on Sunday—to the following Saturday. There were present at the opening the King and Queen of Denmark, the King and Queen of Greece, the whole of the Royal Family, the Corps Diplomatique, the President of the Rigsdad, the representatives of science and learning, and the members of the Congress. Professor PANUM was worthily elected president. The scientific work of the Congress has been described in some detail in our columns, and we need here only indicate the chief communications. The most brilliant and original of these was the paper by Professor PASTEUR on Pathogenic and Vaccinia Microbes, in which he emphasised the intensity of the pathological processes and the morbid poison in the medulla oblongata of animals affected with hydrophobia, and gave details of the wonderful demonstration of the way in which he has rendered animals proof against this disease by inoculation with the poison after its transmission through monkeys. The discovery that one kind of animal can mitigate the virulence of the morbid product of another is one of the most remarkable and significant of any that has been made in the history of the race, and is still only in its infancy. It was generous of M. PASTEUR to credit EDWARD JENNER, by his vaccination work, with making his own discovery more easy, but his generosity will not prevent mankind from extending to him equal praise for investigations that extend our idea of the relations and duties of different members of the animal kingdom, and raise our hopes of fresh triumphs over the most horrible of diseases

Digitized by Google

affecting man and animals, and our estimate of the value of medicine to mankind. The communication of Dr. TOMMASI CRUDELI on Malaria and its dependence on a living organism, favoured by certain conditions of soil and temperature, and the value of arsenic in malarious disease, deservedly attracted much attention. Our readers are in full possession of his views. Sir WILLIAM GULL read what may prove a very important paper on the International Collective Investigation of Disease. Sir WILLIAM so warmly commended this subject to his audience that it had a truly great reception, and was warmly endorsed by the President. One of the most interesting communications read was that of Dr. AUSTIN FLINT on Auscultatory Sounds. Prof. ESMARCH opened a discussion on the subject of Antisepticism in the absence of Sir JOSEPH LISTER, which was one of the most conspicuous, as it was one of the most disappointing features of the Congress. The Scandinavian countries have been foremost in the appreciation of the antiseptic system of surgery, not the least testimony to which and to its distinguished living leader was expressed by the whole Congress rising in honour of him and his system. British surgery, however, was well represented in his absence by Sir JAMES PAGET, Sir SPENCER WELLS, Mr. BRYANT, Mr. KNOWSLEY THORNTON, Dr. MCEWEN, Mr. HENRY MORRIS, and others. English surgery, both in its aspects of safety and boldness, could not have had better illustrations than in the contribution on Colotomy, by Mr. BRYANT; on Nephrectomy and Nephrotomy, by Mr. THORNTON; and in that on Genu Valgum, by Dr. MCEWEN. Our readers will remember with pleasure two other communications to the Congress—one, by Professor MALLING HANSEN, containing some remarkable observations on the Normal Increase of Weight during later Childhood (from nine to sixteen years), and one by Professor PANUM, on Investigation of Food Rations for Men in Health and Disease. The country to be next honoured by the Congress is the United States.

Other Medical Associations.

Our notice of the Congress necessarily curtails our space for the notice of meetings of other Medical Associations.

The British Medical Association met in Belfast. The most noticeable features of the meeting were the Address in Medicine by Dr. ORD on some Disorders of Nutrition related with Affections of the Nervous System, Dr. REDFERN's Address on Physiology, and a communication by Dr. MADDEN on Alcoholic Disease in Children. The Reform Committee was under the painful necessity of explaining its conduct in accepting Sir LYON PLAYFAIR'S amendment of the Medical Bill; in other words, its unfaithfulness to the cardinal principle of all Bills for promoting medical reform, after having striven for it for fifteen years or more.

Among other associations, we may notice the meeting of the fifth International Congress of Hygiene at the Hague in August, the third of the Otological Congress at Basle, and the annual meeting of the British Dental Association. In connexion with this meeting, we may express our concurrence with the President in thinking that it is no slight discredit to the dentists that they are so slow to establish any theory of the decay of the teeth, which seems more general than ever under conditions of civilisation and with an unprecedented development of the dental specialty.

The Medical Profession and Legislation.

The Legislature, not to say the Government, have this year deeply disappointed the medical profession. The Medical Bill, based on the recommendations of a Royal Commission, was promptly reintroduced in the House of Lords by the Government; it was pressed heartily, and passed without difficulty. But on the second reading in the House of Commons the Bill was faintly praised and indirectly condemned by most of the medical members of the House, and by Sir LYON PLAYFAIR, who, in the previous year, had been a hearty supporter of the Bill. He soon after gave notice of an amendment aiming at the most fundamental clauses of the Bill, that providing for a conjunction of all the authorities for licensing to practise, and the Government soon showed signs of weakness. One of the many fallacies with which he misled the House was in the statement that the natural waste of the profession was 1600 a year. He wrecked the Bill, and with it, in a great measure, his own reputation and fitness to represent the medical profession. Without his opposition that of the Home Rulers might have been met and resisted. But he well knew that he was imperilling the Bill when he began to haggle with the Government in reference to giving up the conjoint principle.

Medico-Legal Cases.

Legal Medicine has had illustrations in practice in almost all its branches. Amongst a number of deaths by poisoning recorded in our pages the following may be noticed:—Arsenic, as usual, heads the list both as regards frequency and interest. At Liverpool CATHERINE FLANNIGAN and MARGARET HIGGINS were convicted and sentenced to death for the murder of THOMAS HIGGINS. During the investigation of this case new facts were brought to light and known ones received confirmation. The public and the profession were horrified at the disclosures of an incentive to homicide offered by a reckless system of life assurance. Chemical analysis has proved that the yellow patches found in the alimentary canals of persons killed by arsenic are not invariably composed of arsenious sulphide, and that lethal quantities of arsenic may be obtained from the viscera several years after burial. In a second case a woman named LEFFLEY took the life of her husband, adding sufficient arsenic to a rice pudding to kill more than sixty adults. It may be here remarked that Drs. VAUGHAN and DAWSON of the University of Michigan, U.S.A., have conducted a series of experiments showing that arsenic injected into the mouth and rectum post-mortem becomes widely diffused in the tissues and organs. A notable instance of death from strychnia was investigated before Dr. DANFORD THOMAS. A woman received from her paramour a powder avowed to consist of calomel, and, ignorant of its nature, she gave it to her father, who died from violent spasms within half an hour. Several other deaths have ensued from poison taken through inadvertence, or supplied by unqualified persons. A pupil at the Gloucester Infirmary, writing from the dictation of a physician, prescribed by mistake a drachm of chloral hydrate in place of the syrup; the patient died. Patent medicines have claimed their victims—e.g., a child succumbed to the action of Indian tincture (? Indian hemp) in a few hours. In one case a woman lost her life through taking lobelia sold to her by a herbalist. The coroner's

Digitized by Google

jury acquitted the vendor on the erroneous assumption that lobelia was not a poison.

The study of animal poisons has made advances in spite of the intrinsic difficulties attending the prosecution thereof. Acute infectious disorders, such as foot and mouth disease, Texan fever of cattle, enteric fever, and puerperal fever, have received attention at the hands of pathologists and medical jurists. It must be admitted, however, that we are far from understanding the *modus operandi* of the morbid material in many instances, but still experience points to the conclusion that danger to health and life is to be apprehended from the direct transmission of the specific virus, and from the ingestion of meat rendered poisonous by toxic agencies generated under the influence of such virus. The opinion has gained ground that the so-called cadaveric alkaloids are largely answerable for the symptoms incidental to the taking of putrid food and tinned animal and vegetable matter. Allied to these "alkaloids," if not actually belonging to the same group, are the principles evolved in certain diseased states of the body. We refer more particularly to the condition known as acetonuria. HOPPE-SEYLER has described a case in which this followed poisoning by sulphuric acid; and in THE LANCET of May 3rd there is recorded a death from "Kussmaul's diabetic coma" of great medico-legal interest.

Three cases of strangulation that have happened during the year deserve notice. In the first of these, known as the "Stoke Newington murder," the victim, a young man, was strangled by means of his own handkerchief, and then thrown into a reservoir. The second case was that of a child found dead in the Surrey Canal, at Peckham, with its neck tightly constricted; it is noteworthy on account of the way the inquest was conducted. No medical evidence was called, the mortuary keeper being the scientific witness. Lastly, there was the murder of ANNIE YATES, a prostitute, living in Burton-crescent, who was found dead with a severe scalp wound and a towel tied round her neck. Supporting the theory of homicide was the fact that her right arm had been for a long time paralysed. In no one of these cases was the offender brought to justice.

Criminal abortion has been largely practised, and very differently punished in different cases. At the Liverpool assizes the capital sentence was passed. At the Central Criminal Court the two convicts escaped with fifteen and twelve years' penal servitude respectively. A woman was admitted to University College Hospital suffering from supposed typhoid fever, but post mortem punctured and lacerated wounds were discovered about the genitals, and in the uterus there were conclusive signs of recent delivery, and around it of cellulo-peritonitis. No clue to the person who procured the abortion has been forthcoming.

Several charges of malpraxis have been preferred against medical men. Two of these were in the colonies, and had reference to alleged neglect at confinements, whereby the uterus was ruptured in one case and wounded in the other. Sentence of imprisonment followed conviction in the former instance; in the latter the accused was acquitted. A surgeon at Hawkes' Bay was mulcted in damages of £175 for supposed unskilful treatment of a broken leg. A German doctor has been convicted of manslaughter because he did not adopt the Listerian method of dressing a wound. We have repeatedly had to criticise the mode of procedure in coroners' courts, and especially as regards the holding of inquests without post-mortem examinations and without medical evidence. The iniquity of the law of criminal responsibility was exposed when GEORGE BALDWIN, an inebriated epileptic, received sentence of death for the murder without provocation of an old man. Justice, however, prevailed over the statute, and the capital punishment was not inflicted. Mere mention of the name of WELDON will suffice to remind our readers of the lamentable defects in the existing Lunacy Acts. The post of Director of Criminal Investigation has been subjected to unfavourable comment, and at length a special committee has reported in favour of radical changes in the working of the office. It remains to be seen whether the executive will act upon the report and proceed with the needed reforms. The large number of queries addressed to us as to the remuneration of medical men for professional services in courts of law shows the system requires definition and codification.

Public Health and Epidemiology.

The first half of the year which is now passing away was not characterised by anything remarkable as regards public health in England and Wales. The general mortality was below the average, and the death-rate from the principal zymotic diseases was also less than the mean for the past ten years. Indeed, apart from some increase of small-pox, which at the time gave rise to anxiety, diphtheria alone, amongst this class of diseases, was in excess, and it is evident from the mortality which is now registered under that heading that this very obscure and often terribly fatal disease is steadily making inroads amongst us. To some extent the increase of registered diphtheria deaths may be due to improved knowledge leading to a more correct diagnosis, but this alone will hardly account for the large number of epidemics that are now so frequently recorded. The third quarter of the year was marked by an excessive death-rate, which was mainly the result of exceptional meteorological conditions. During the latter part of the second quarter of the year the rainfall was below the average, but during the third quarter the diminution was more marked, being 2·87 inches below the average; and this condition was associated with an excessive temperature. Indeed, during the month of August the excess above the average amounted to over 4° F. These two conditions coming concurrently into operation have always tended to an increased diarrhœa fatality, and during the past quarter the death-rate from that cause alone amounted to 2·7 per 1000, as opposed to an average of 1·9. Large towns were, as usual, mainly affected—Leicester, Preston, Nottingham, Northampton, and Norwich taking the lead. Owing to the prevalence of cholera on the Continent of Europe a larger proportion than usual of the diarrhœa deaths was attributed to cholera, but with one or two exceptions, to be referred to later on, there is no reason to believe that this disease succeeded in reaching this country. The prevalent drought led also to considerable difficulties as regards water-supply, and during the third and fourth quarters of the year considerable local outbreaks of disease resulted. Two outbreaks were of special magnitude—namely, those from enteric fever at Beverley and Kidderminster. Both were ascertained to be related to

Digitized by Google

conditions of water-supply, and although the reports of the inspectors of the Local Government Board who inquired into them are not yet issued, yet it may be fair to assume that the sources of supply were in both cases influenced by the excessive drought which had preceded them. Small-pox bids fair before the close of the year to give some decided indications of a coming epidemic. The disease resisted the onset of summer weather for a longer period than is usual, and it has not failed since to show that many of the conditions favouring a large prevalence exist in several parts of the kingdom, and especially in the metropolis.

The present year is memorable in connexion with the epidemic of cholera, which, appearing first in the south of France, spread rapidly into Italy, and later on to Spain, Algeria, and then to Paris. The disease was in the first instance imported from the east into Toulon in June; thence it rapidly spread to Marseilles, some 900 and 1700 fatal attacks respectively occurring in those two cities. A large number of places in the south of France soon became invaded, one of the worst outbreaks being at Perpignan. From France the disease spread first into Italy and later on into Spain. The Spanish outbreak was not on a large scale; it was mainly confined to the coast province of Alicante and one or two other places, and no trustworthy statistics of its mortality have been published. The invasion into Italy was, on the contrary, of great severity. Commencing in August, the infection was rapidly diffused throughout a large portion of Northern Italy, Spezia being specially affected and suffering a loss of some 600 lives. Thence the disease was conveyed into the province and city of Naples, and some 7000 deaths, the majority of which took place in the city, were the result. In all, there cannot have been less than between 10,000 and 11,000 cholera deaths in the kingdom of Italy, and the disease clung with special tenacity to towns, such as Naples, Spezia, Genoa, &c., which had water-supplies subject either to constant or to occasional contamination; whilst, on the other hand, several importations of the infection into Rome, where an admirable water service is available, failed to bring about any spread. Early in November cholera was conveyed into Normandy, and a few days later the infection was announced as having reached Paris. In this city the mortality rose till it reached its highest point about the middle of the month; then an abatement commenced, and at the end of the month, when somewhat under 900 fatal attacks had been recorded, the epidemic as such was considered to have ended. Occasional cholera deaths, however, still occur in Paris, and the prospect of a recrudescence of the disease next year imposes on our sanitary authorities the great responsibility of being prepared in advance with an organisation which shall secure the detection and immediate isolation of the earliest attacks. On two occasions the disease has reached our shores this year. The most important importation was into the port of Cardiff, but owing to the system of medical inspection and to the means of isolation which were there available the infection failed to spread on shore. So far then, our national system of defence against cholera has served us well, and the experience recently gained from the working of the alternative system of quarantine, whether by land or by sea, in Southern Europe, has been such as to prove abundantly that in this matter England has chosen the good part. Unless our system is coupled with national and individual efforts to secure the utmost possible cleanliness in all our surroundings, it is hardly likely to prove in all points successful, but it can never fail more signally than quarantine has done.

The International Health Exhibition.

Another striking feature of the year has been the International Health Exhibition. Its success as an attraction was prodigious, though the financial result is likely to be more moderate than might have been expected. Our elaborate reports will be our best excuse for not noticing the Exhibition here at greater length. The Biological Museum, under Mr. CHEYNE, was perhaps the most valuable part, as it was the least frequented, of the Exhibition, and, let us hope, will prove the fair beginning of a State-endowed laboratory for the study of pathogenic organisms.

Miscellanea.

We cannot now detain our readers with any lengthy allusion to miscellaneous questions, which, however, are legion. No great honours have been awarded in the course of the year to the profession; the only one we recall, and that well deserved, was the promotion of Dr. ACLAND to the rank of Knight Commander of the Most Honourable Order of the Bath. The sympathy of the profession has been strikingly shown in several instances, notably in the fund raised in a few days to help Messrs. BOWER and KNATES to meet the legal expenses to which they have been put by a series, not yet completed, of heartless and harassing prosecutions, which, in the estimation of the judges, were entitled to the name of persecution. The historical expansion of national education in the last fourteen years has led to much misgiving as to the physical effects of school pressure on the children of the poor. At the request of Mr. MUNDELLA, Dr. CRICHTON BROWNE investigated this question from a medical point of view. His report was held back until its unfavourable suggestions could be counteracted by the concurrent publication of a report by a lay official of the Education Department, Mr. FITCH. This questionable device on the part of the Vice-President of the Council did not suffice to remove the wide impression produced by Dr. CRICHTON BROWNE'S report, which has been generally endorsed by the profession, and which will yet have far-reaching effects in modifying the pressure of school work. One of the most significant events of the year has been the appointment of a Royal Commission to report on the Dwellings of the Poor. Not the least noticeable feature of this Commission is that it is presided over by His Royal Highness the Prince of WALES, who has shown great personal interest and taken much personal trouble in the matter. The whole "case" of the poor is being "considered" by the rich with an unprecedented care, which speaks well for the future of both classes. In the spring the University of Edinburgh celebrated its 300th year of existence with rare proofs of its world-wide and well-sustained reputation, in spite of certain little parochial feelings which led it into unworthy opposition to the Medical Bill, and have not raised respect for it in the profession in England during the year. Various circumstances have lately directed English, and especially London, opinion to the monstrous absence in the metropolis of a Teaching University, and a powerful move-

Digitized by Google

ment is on foot for supplying this great defect. We were among the first to expound this great need, and we shall not fail to support any well-devised scheme for placing London in this respect on a level with every other capital in the civilised world.

As on the borderland between Physiology and Sport, we may here notice the wonderful feat of Mr. WESTON, done under teetotal conditions, of walking fifty miles a day for a hundred days, Sundays and Christmas-day excepted. The feat was the more remarkable as Mr. WESTON set out with a bad cold, and suffered at first for weeks with a sore foot.

Obituary.

Death is seldom a welcome visitor, but in few years has he been less so than in the present, having removed many from our ranks who, to all human seeming, were destined for years of service and the achievement of fame. We can only, at a venture, recall a few of the names which have appeared in our obituary this year. Mr. PETER EVERSHED is a man to be mentioned. Born in the last century, in practice with his father before most of the present heads of the profession were born, a lover of nature, an enthusiastic fox-hunter, riding to hounds, and "riding well forward" up to his eighty-second year, he had time and strength for fifty years' continuous and honourable practice in the same village (Billingshurst, Sussex), and then for more than twenty years of "blest retirement." At the other end of life, and all too soon, we have had to record the death of ALEX. BAIRD, of Perth, whose contributions to our columns in the form of "Scottish Notes," from the bed to which he was long confined by paraplegia, were read with interest by many far beyond the limits of Scotland. Dying at the age of thirty he showed what are the risks of the medical profession. He had, at various times, incurred typhus, small-pox, and blood-poisoning, the latter in 1880, ending in myelitis, from which he never recovered. His energy and his geniality survived the typhus and the small-pox, and even the myelitis, and he wrote and worked to the last like a man without trouble or disease. When shall we end if we give way to the thoughts that rise in us as we recall the names of JOHN NETTEN RADCLIFFE, of FREDERICK A. MAHOMED, of ALLEN THOMSON, of JOHN HUTTON BALFOUR, of A. WHYTE BARCLAY, of J. HALL DAVIS, of GEORGE MAY of Reading, of FAIBLIE CLARK, of ALEXANDER TWEEDIE, of WILLIAM TAYLOR, J.P., of Scarborough, of HENRY WALKER, J.P., of Brierley-hill, of ARMAND LESLIE (killed at the battle of Teb), RICHARD SUMNER of Formby, Liverpool, ALEXANDER WOOD, CÆSAR H. HAWKINS, Sir ERASMUS WILSON, FREDERICK CHAMBERS, J.P., JOHN POPHAM, SAMUEL RABBETH, THOMAS CHAVASSE, GEORGE LUMGAIR, and DANIEL J. DUIGAN, Deputy Inspector of Hospitals; to say nothing of men of other nations, such as Prof. GROSS of Philadelphia, the "Nestor" of American Surgery, of COHNHEIM, of JEAN BAPTISTE DUMAS, &c. &c. The names speak for themselves, and will recall all that is thorough in science, all that is faithful in professional service, if they also illustrate the risks and the endurance of professional life, whether in civil or military conditions. Neither can we withhold here a word of respect and regret for Mr. B. R. WHEATLEY, the Librarian of the Royal Medical and Chirurgical Society, whose arduous and faithful labours and courteous and kindly manners will be long and gratefully remembered by the profession.

Conclusion.

We must now leave our readers for the year with all good Christmas sentiments. While individual members of the profession disappear, the great army of healers remains, and will remain to do brave battle with disease. THE LANCET grows apace with the growth of professional and scientific news. Ten years ago 64 pages sufficed to deliver our weekly message to the profession. These have been quite inadequate of late, and 96 and even 104 pages are now needed for this purpose. We can only rejoice to be able to meet the ever-widening demands on a journal which aims at the double function of being on the one hand a medium of medical news, science, and literature, and on the other of leading the public to a higher appreciation of the claims and labours of the profession, and which in both capacities meets with so generous a reception at home and abroad.

Annotations.

"Ne quid nimis."

WELLINGTON COLLEGE.

SINCE we called the attention of our readers for a second time, to the unsatisfactory state of health at Wellington College (THE LANCET, Dec. 13th, 1884), we have received communications, chiefly from the parents or other near relatives of boys, which tend to confirm the opinion we have expressed that there is something seriously wrong with the sanitary condition of the College or its surroundings. We are well aware of the objection which attaches to information thus received, that it is *ex parte*, that many of the circumstances adduced in support of it might be satisfactorily explained, and that in some instances, at least, the complaints may be unfounded, or exaggerated. But making all allowance for these possibly sources of error, there is yet enough to justify us in maintaining that a strong *prima facie* case has been made out for an inquiry, by a competent and independant body, into all the circumstances bearing on the health of the boys. Such a course is imperatively necessary in the interests of the College, for until some assurance has been given that these boys are, as far as possible, protected from preventable disease, we may fairly presume that many of the parents will send them to other schools where such matters are known to receive the necessary attention. It is also demanded in the interests of the Governors, for it will be a serious blot on their reputation if the School falls off in consequence of their neglect, real or supposed, of so important a duty. And it is, most of all, requisite, in the interest of the boys, for, in addition to the risk of life involved in the neglect of sanitation, there is the certainty that the health of some—who can say how many?—may be permanently injured and their future career impaired as a result of disease which might have been prevented by the adoption of judicious measures. We have done our duty in bringing the subject under public notice, and we have suggested the course which seems to us to be the best fitted to meet the case; it remains for the parents of the boys, many of whom are in a position which puts it quite within their power, to demand an inquiry into the state of health of the school, and an examination by skilled experts, medical and engineering, into the sanitary state of the College and its surroundings, and of the masters'

Digitized by Google

houses. But the investigation must be conducted by men entirely independent of the College, the results must be unreservedly made known, and the measures which may be deemed necessary to improve the health must be carried out as promptly as possible. Unless some such course is adopted, it can scarcely be expected that Wellington College will maintain its numbers or continue to hold the position it has attained in the public estimation as one of our great and deservedly popular public schools.

DEATH FROM COMBINED EFFECTS OF ALCOHOL AND MORPHIA.

ON Monday, Dec. 22nd, the deputy coroner for Central Middlesex held an inquiry into the cause of death of Thomas Rice Webber, aged twenty-seven years. The deceased, habitually a temperate man, appears to have indulged freely in alcohol on the day previous to the fatal event. Soon afterwards his symptoms were those of "acute mania," and so violent was he that physical restraint had to be resorted to. Mr. Hazell, jun., of Oakley-square, was consulted, and this gentleman, to quiet the ravings of the patient, administered three-quarters of a grain of morphia by hypodermic injection. Within forty minutes sleep was induced, from which the deceased never awoke. Death ensued in about six hours. The post-mortem examination was conducted by Mr. Pepper in the presence of Mr. Hazell and another medical man. Beyond a few trifling bruises on one leg there were no marks of violence on any part of the body. All the internal organs were passively congested, indicative of the mode of dying. The mitral and aortic valves showed signs of previous inflammation, but the vegetations were small and dense. The left ventricle was moderately hypertrophied without dilatation. The brain was healthy. In short, there was neither albuminuria nor acetonuria; no disease was discovered sufficient to account for death. Mr. Pepper gave it as his opinion that the deceased succumbed to the combined effects of alcohol and morphia, and that the issue was accelerated by the exhaustion consequent on excessive mental and physical activity. The jury returned a verdict in accordance with the medical evidence, the same time acquitting Mr. Hazel of all blame. The above case is interesting on clinical, pathological, and medico-legal grounds. It shows the danger to be apprehended from morphia narcosis in conditions like those above enumerated, and the extreme care that should be taken when dealing with symptoms, and causes of death of doubtful and, perhaps, undeterminable quantity.

SMALL-POX AT SHEFFIELD.

IT is questionable whether the best way of bringing the objectors to vaccination to their senses is not to allow small-pox to have full sway amongst them. But this is a disastrous way. So we put on record from time to time overwhelming arguments, or rather facts, which to all reasonable people are enough. A very instructive paper by Mr. C. H. Willey, M.B., the superintendent of the Borough Hospital at Sheffield, giving his experience of the effect of vaccination in modifying small-pox, has been published for wide circulation in Sheffield, and is well fitted for distribution everywhere. It tells the same story that every similar report carries. There were 210 cases. Of these 157 had been vaccinated in childhood, 4 had been revaccinated, and 49 unvaccinated. To professional eyes the most striking part of this report is the occurrence of four cases in revaccinated people. But surprise is reduced to a minimum by the actual details of the cases. Thus, in three of the four the operation was not performed till *after* the patients had contracted small-pox, in the remaining case thirty-six years had elapsed since the revaccination was performed. It is not stated how far even that revaccination was successful. Of the 157 vaccinated cases 7 died, or a percentage of 4½. Of the 49 unvaccinated cases 14 died, or 28½ per cent. The difference in the severity of the disease in the vaccinated and the unvaccinated was great. In the vaccinated it was mild in 122 out of 157 cases. In no less than 47 out of the 49 unvaccinated cases the disease was of the more severe kind. The disablement for work was in the revaccinated 13½ days, in the vaccinated 22 days, in the unvaccinated 42 days! The complications of the disease occurred in 11½ per cent. of the vaccinated and in 71 per cent. of the unvaccinated. Three patients lost the sight of one eye—they were all unvaccinated. Among the *employés* of the hospital not one took the disease, all having been revaccinated on commencing duty. The committee of the Sheffield Borough Hospital do a good public service by the publication of these facts. They reveal nothing new to those familiar with the question. But every fresh illustration of the truth carries conviction to minds that are capable of weighing evidence. As for the minds in which this capacity does not exist—well, they prefer small-pox with six weeks' disablement, the risk of losing one or both eyes, permanent disfigurement, and a still greater risk of losing their life to the slight inconvenience and infinitesimal risk of vaccination. Of two evils they choose the larger one.

MR. WALLEY ON VETERINARY WORK.

THE inaugural address of Principal Walley at Dick's Veterinary College, Edinburgh, dealt with most of the topics now uppermost in the domain of veterinarian science and practice. He began by speaking of the recent pathological researches based upon the germ theory, and expressed the opinion that the ends attained had not been commensurate with the means employed to gain them. The all-important question was to know how to grapple with these diseases, and he boldly asked whether this knowledge was to be gained by the pursuit of experiments to test theories, or attempts to discover by experiment a physiological antidote, rather than by the adoption of energetic measures to stamp out the disease. When sheep-pox prevailed, twenty years ago, it was the practical, and not the scientific school that succeeded in arresting the plague. In checking the ravages of the rinderpest, which system, he asked, gained the day, the vaccination of the doctors or the science of the veterinarian? Years, and even valuable human lives, had been spent in the vain endeavour to find a [illegible] antidote for glanders; but we know that the disease can be arrested by enforcing a few practical regulations. Contagious pleuro-pneumonia was another instance of a disease in which protective inoculation had been attempted with such partial success as to be replaced by purely practical measures. As to rabies, he considered that science engaged in finding an antidote is playing with the malady which the experience of Edinburgh has shown can be exterminated by "purely practical measures in much less space of time, and with much less attendant danger to man and suffering to animals, than it can ever be by the adoption of purely scientific measures." The same seemed to be true of anthrax; and quoted the discrepant opinions of Pasteur and Koch as regards the value of protective inoculation in this disease. The discovery of the anthrax bacillus was of little value in veterinary practice, for it had not added to our knowledge of prophylaxis. At the same time Principal Walley did not wish to undervalue the efforts made to determine the true nature of these and other infective diseases; he desired rather to impress on his hearers the need of becoming fully acquainted with the measures to be taken to arrest the spread of these maladies. He dwelt at length upon the great importance of [illegible] and criticised severely the prevalent indifference to [illegible]

Digitized by Google

in the housing of animals, which, indeed, has been shamefully neglected. It is the same with the food-supply and the evils of adulteration, which appear to abound in cattle-feeding, and in respect to which the British National Veterinary Medical Association is about to take action. Lastly, he referred to the need for humanity to animals, and took as an instance of the want of this the unnecessary and wanton practice of overstocking the udders of cows. We trust that his eloquent denunciation of this practice will have effect in causing its abolition.

PEPTONISATION.

AN observation communicated by M. Marcano to the Academy of Sciences is suggestive of what may prove a valuable process for the conversion of albuminoids into peptones. If a small quantity of the fresh sap of certain plants—the agave, for example—be added to chopped meat first covered with water, and the mixture be kept at a temperature of 39° to 40° C., an active fermentation is immediately set up, with evolution of inodorous gases. At the end of thirty-six hours the fibrin has disappeared and a liquid is left containing peptone equal in weight, when dried in a stove, to one-fifth of the fresh meat used. This fermentation appears to M. Marcano to be due to the vital action of micro-organisms, and to resemble the peptonisation of the gluten of flour by a bacterium which is said to take place in bread-making. In confirmation of this view it is stated that if the juice of the plant be saturated with chloroform the fermentation is not set up. Moreover, a "mucorinée" may be cultivated by sowing a few drops of agave sap in sugared water. This mucorinée is capable of completely dissolving fibrin in the presence of water. A large number of other fruits and juices are stated to be endowed with properties similar to those possessed by the sap of the agave. Papaw juice is said to be relatively weak compared with the peptonising activity of other juices which contain no digestive principle like "pepsin." M. Marcano is of opinion that the new method of peptonisation will afford a simple and economic means of preparing pure peptone quickly and at a low price, and suggests that it might be applied upon a large scale, so as to allow of the export of meat from South America in a form more nutritious and economical than the extracts.

THE UXBRIDGE TRAGEDY.

ON Friday last Elizabeth Gibbons, charged with having murdered her husband at Hayes, near Uxbridge, was convicted and sentenced to death at the Central Criminal Court. The proof of her guilt was to all intents and purposes sought to be established by circumstantial evidence, positive and negative. It was contended by the prosecution that James Gibbons, the husband, a well-to-do man, had not shown signs of previous mental aberration, and that on the night of the alleged murder he was cheerful in his manner. It was not denied that the revolver with which the fatal shots were fired was purchased by the deceased, at the same time there was nothing to show that this was done with the intention of using it for suicidal purposes. To our minds the case as presented to the jury hinged mainly on the question of motive, and we maintain that no sufficient motive was proved. It can scarcely be urged that a woman fifty-four years of age, who had lived in good-will with her husband for thirty-seven years, would of malice aforethought "kill and slay" him because of a feeling of jealousy aroused by an attachment of the latter to a child only just entered her teens, and yet this was the strongest point laid before the jury by the Crown lawyers. In Mr. Gilbert's play, "Pygmalion and Galatea," the relentless Cyniska, who it might be assumed was fired by the restless passions of youth, was content with solemn invocation to the goddess Artemis to call down blindness on her backsliding spouse. How little likely then that an elderly matron should with her own hand *deliberately* take the life of him on whom she depended for protection and sustenance? We do not say that such an explanation is not possible, but surely it is far removed from probability, and the underlying facts themselves were not, we submit, proved beyond "reasonable doubt." What, on the other hand, were the antecedents of James Gibbons? Suicidal tendencies were asserted to have existed in his family, and although nothing more than this and depression of spirits were put forward in support of the theory of his insanity, it must be borne in mind that they are frequently the only known precursors of an outbreak of madness of a most dangerous form. It did not at all follow because a bullet wound was found on the body of the deceased in such a situation that it could not have been self-inflicted that therefore it proved a criminal act by another person. It might have resulted from accident during a struggle for possession of the revolver, or from "justifiable homicide" for self-preservation. At most, in the absence of adequate conscious motive, the act was done in a sudden phrenzy, when the promptings to crime were no longer subordinated to the will; but then this is not murder.

Obviously the prisoner in this case *must be* respited. The inferences of the medical witnesses were at variance with similar known facts in other cases on record, in which a shot has been fired by a suicide in the interval between the infliction of a mortal wound—even of the heart—and death. Moreover, a wound in the back is peculiarly likely to be self-inflicted if the suicide falls forward or on his side while the arm, still clutching the pistol, is convulsively drawn, stiffened, and by the fall twisted back. We must confess our inability to understand how it came to pass that these well-known facts were not brought under the notice of the Court at the trial. A petition to the Home Secretary, praying for the respite of Elizabeth Gibbons, lies for signature at our office.

IMPRUDENT MARRIAGES.

AN inquest held lately at Whitechapel deserves comment, not only on account of the case involved, but also because of a remarkable opinion delivered in connexion with it. Matilda Buckham appeared before the coroner, Mr. Collier, to give evidence touching the death of her infant, aged three months, which was found dead in bed beside her. The child was the last of a family of seven, all of whom were dead. Of these, three had been the subjects of inquest, and all had died of convulsions or other allied disorders. The mother herself was an epileptic, and had a fit in court immediately after giving evidence. The verdict returned on the child's death was "Suffocation in bed," and the jury concurred in an observation by the coroner that the Legislature ought to make marriage on the part of persons suffering from such diseases as the mother's a penal offence. It is easy to see how one who witnessed a scene like that in the coroner's court on this occasion, especially after hearing evidence so strongly suggestive of hereditary disease, might feel himself impelled to fortify the verdict in the terms above mentioned. It is, however, a different matter when we come to the actual work of legislation. It may be theoretically correct and advisable that persons strongly tainted with transmissible disease should not marry, but the Government which would undertake directly to prohibit even such a union must incur a grave responsibility. It would assume to restrain personal conscience and liberty in respect of a most fundamental law of nature, and must be able to define the point at which a multitude of morbid states become insufferable, a point unknown to medicine. Further, its responsibility must extend to the regulation of the results

Digitized by Google

which might arise in consequence of its action on the lives against whose continuance it had in a sense given judgment. What Government is sufficient for these things? Injunction informed by educated reason must, we think, mark the limit of judicious interference in such a matter, and this is permissible to all persons.

CONDENSED MILK.

MR. THOMAS MABEN, of Hawick, N.B., has presented to the Pharmaceutical Society an interesting paper on Condensed Milk. In conjunction with Mr. Dechan, Mr. Maben has analysed ten different kinds of condensed milk, seven of them sweetened and three unsweetened. In the former the water amounts to only about 30 per cent., whereas in the latter it varies between 64 and 69 per cent., the difference being made up by cane sugar. The unsweetened milk is concentrated to rather less than one-third of its original volume, but different brands show different strengths. To bring it to the ordinary standard of strength from two to three volumes of water can be added to it, but no more. The sweetened milk seems to contain about the same percentage of casein, fat, milk-sugar, and salts; but Mr. Maben points out that for infants' food it will stand much greater dilution, inasmuch as the cane sugar is a valuable element of food. He prefers to use a mixture of one part of the condensed milk with eleven of water. Such a diluted milk would, however, be much weaker than woman's milk, with which he compares it, and a more close resemblance would be produced by adding five parts of water to one of the sweetened condensed milk. It is quite true that nurses often use the condensed milk in too large quantities; but we confess that we are inclined to think that Mr. Maben errs on the other side. As to the general question of the use of condensed milk instead of ordinary cow's milk for infant food, we can confirm the experience of the medical friend whom Mr. Maben quotes. We have known infants who constantly suffered from diarrhœa, green stools, and the like, when fed on ordinary cow's milk, but who recovered at once on condensed milk. Of course we do not say that this is always the case.

EXTENSION OF THE PENNY DINNER MOVEMENT.

ON Dec. 6th a meeting of representative School Board managers and others was held at the Society of Arts, Adelphi, to consider the subject of penny dinners for school children. Mr. Sydney Buxton, M.P., presided. In his opening remarks Mr. Buxton dwelt on the close connexion between over-pressure in school work and insufficiency of food. He urged the importance of settling the difficulty as to nutrition without recourse to aid from the Government. Mr. Mundella, in an address of considerable length, referred to the Jews' School in Spitalfields, and the schools under the penny-dinner system of Sir Henry Peek at Bonsdon, and of the Rev. Mr. Moore Ede at Gateshead, in illustration of the happy effects of a cheap and wholesome diet in resisting the strain of educational work. He bore personal testimony to the sound and palatable character of the food supplied to children at the rate of one penny per meal. The Rev. Mr. Ede also gave some interesting details of the working of this plan in his own neighbourhood. Though a penny was the fixed rate of payment, it was found in practice that when many children dined together, while there was no stinting, the rate of consumption was distinctly under a penny per child, a margin being thus left which was sufficient to cover cooking expenses. Mr. H. Forbes Clarke read a statement showing that the penny dinner was already an institution in fifteen Board Schools, and was favourably regarded by the managers of others. His catalogue of the various viands set before the children sufficiently proved the substantial nature of this movement. The meeting, we are pleased to note, did not separate without appointing a Central Council, consisting of influential sympathisers with its object, under the presidency of Mr. Mundella, to assist the various local committees in placing this simple and efficient system on a self-supporting basis.

CLINICAL AND PATHOLOGICAL SOCIETIES.

THE officers and council of the Clinical Society proposed for election for the year 1885 are as follows:—President: Thomas Bryant. Vice-Presidents: J. W. Ogle, M.D.; J. Andrew, M.D.; W. Cayley, M.D.; A. E. Durham; W. M. Baker; T. Pickering Pick. Treasurer: Christopher Heath. Council: H. R. Crocker, M.D.; Sidney Coupland, M.D.; A. W. Edis, M.D.; W. Ewart, M.D.; D. W. Finlay, M.D.; F. de Havilland Hall, M.D.; D. B. Lees, M.D.; F. Semon, M.D.; T. G. Smith, M.D.; J. Williams, M.D.; A. E. J. Barker; H. H. Clutton; M. C. Davies-Colley; C. Dent; A. P. Gould, M.S.; J. W. Haward; R. C. Lucas; J. H. Morgan; H. Morris; G. Ransford. Hon. Secretaries: Stephen Mackenzie, M.D., and R. J. Godlee, M.S. The officers and council of the Pathological Society proposed for election for the year 1885 are the following:—President: John Syer Bristowe, M.D., F.R.S. Vice-Presidents: H. Charlton Bastian, M.D., F.R.S.; W. Cayley, M.D.; G. Johnson, M.D., F.R.S.; S. Wilks, M.D., F.R.S.; A. E. Durham; J. W. Hulke, F.R.S.; George Lawson; T. P. Pick. Treasurer: John Wood, F.R.S. Hon. Secretaries: J. F. Goodhart and H. T. Butlin. Council: Robt. Barnes, M.D.; A. E. J. Longhurst, M.D.; Norman Moore, M.D.; J. F. Payne, M.D.; G. V. Poore, M.D.; F. T. Roberts, M.D.; Felix Semon, M.D.; S. J. Sharkey, M.B.; F. C. Turner, M.D.; S. West, M.D.; A. E. J. Barker; W. W. Cheyne; H. H. Clutton; W. H. Cripps; F. S. Eve; C. H. Golding Bird; A. P. Gould, M.S.; R. C. Lucas; H. Morris; L. G. Shattock.

CRUELTY TO ANIMALS.

WE regret to read that when the Pulborough sparrow-shooting case again came before the magistrates at the Petworth Petty Sessions on Saturday last, the Chairman (Mr. Peachy) said they had, in compliance with the decision of the Court above, to pass sentence, but the Act (the Wild Birds' Protection Act of 1880) provided that for a first offence the Bench could only reprimand the defendants and order them to pay the costs. He accordingly reprimanded them; and the costs, which in some cases amounted to 11s., and in one to 24s., were paid by the defendants. Seeing that Mr. Justice Hawkins, when sending back the case to the magistrates to convict, had expressed a hope that "when they do convict they will pass an exemplary sentence on all who took part in the brutal sport of shooting at these wretched birds," we can only express our astonishment and regret at the law's apparent inadequacy to give effect to such a strong expression of opinion on the part of a judge.

BUILDING ON DISUSED BURIAL-GROUNDS.

TAKEN in conjunction with the ravages and recent decline of cholera in Paris and on the Continent generally, and with our own immunity so far from that justly dreaded disease, the recent judgment by Mr. Hannay, since confirmed by a superior court, with reference to the opening up of the Old Peel Burial-ground in Bethnal-green must appear to be one of very questionable propriety. In opposition to the Metropolitan Board of Works, he has maintained that the area in dispute does not come within the operation of a bye-law of the Board, which forbids the use for building purposes of land impregnated with animal or vegetable matter before the removal of the soil so affected,

Digitized by Google

and he has accordingly sanctioned the erection of buildings upon it. Now, the Old Peel Burial-ground was during the cholera epidemic of 1849 literally packed with the remains of the victims of this malady. There is nothing to show to what extent the contagion then entombed has been starved out of existence during the subsequent period in which the ground has been unused. It may very well be that under the favouring conditions of sufficient heat and moisture which the earth of cemeteries is known to furnish the germs of disease are still preserving a subterranean life. There is no slight risk in such a case that the drainage and water-supply of the houses to be built at this spot will become the conduits of infection. It were therefore better in our view that a soil once so impure should be left altogether undisturbed; but if the time for this possibility is past, there only remains the greater necessity for the removal of all contaminating matters and the thorough disinfection of the sites to be occupied. These observations, which apply in a special degree to the case before us, have, moreover, a practical significance which should not be forgotten in dealing with the same subject in all its aspects.

THE London correspondent of a Northern contemporary states that the inquiry into over-pressure by the London School Board is likely to collapse, as the Board has refused to sanction the payment of retaining fees for medical evidence. A compromise has been effected in the committee, to the effect that the medical expert's evidence is not to be received as final, but, subject to the deliberations of the committee, is to be treated as evidence only; it is, however, unlikely that the majority of the Board will rescind their resolution on the subject.

FROM the report made by Messrs. Crookes, Olding, and Tidy on the composition and quality of daily samples of the water supplied to London during the month of November, it appears that of the 172 samples examined, all, excepting one which was recorded as slightly turbid, were found to be perfectly clear, bright, and well filtered. The proportions of organic matter present in the water have continued low, and below the average for the season of the year, though not to so exceptional a degree as in the samples examined in the preceding month.

THE *Surrey Advertiser* says:—"The Farnham Board of Guardians has done well, we think, to vote a gratuity of £10 to Dr. Young, of Aldershot, for extra services connected with the outbreak of diphtheria at Ash and Normandy. In such cases it is well thus publicly to recognise the valuable services of medical officers, who, as with the ability and devotion manifested on this occasion by Dr. Young, render such important services to the community at large."

DR. N. TIRARD has been elected Professor of Materia Medica to King's College, and Assistant-Physician to King's College Hospital, in succession to Professor Baxter, who has been compelled to resign these offices from ill-health.

THE announcement that Dr. R. von Leudenfeld has discovered histological elements having nervous functions in the sponges of the Australian shores possesses considerable interest for biologists.

MR. D'A. WENTWORTH THOMPSON, of Trinity College, Cambridge, has been appointed Professor of Biology at University College, Dundee.

MR. F. C. CARR-GOMM has succeeded Mr. J. H. Buxton as chairman of the House Committee of the London Hospital.

ANOTHER CHOLERA MICROBE.

AT a recent meeting of the Medical Society of Munich Privat-Docent Dr. Rudolf Emmerich gave a preliminary account of the observations which he had made in connexion with the epidemic of cholera at Naples. The paper will be published in the forthcoming number of the *Archiv für Hygiene;* but having been favoured with the perusal of an early proof, we avail ourselves of the opportunity of placing some of the more striking features of its contents before our readers. Dr. Emmerich was specially sent to Italy by the Bavarian Government for the purpose, as he says, of making a pure cultivation of the Bacillus Asiaticæ Kochii, and of bringing it back with him to Munich in order that its properties might be investigated. He was accompanied by Dr. Escherich, who volunteered his assistance.

Feeling, however, that the mere finding of a peculiar microbe in the intestinal contents, and apparently nowhere else, in cholera was not sufficient to account for the disease, Dr. Emmerich did not limit himself to searching for comma-shaped bacilli, but determined to ascertain whether he could not bring to light, by means of cultivations in various nutritive media, the existence of specific organisms in the tissues and organs of cholera-affected persons. He reached Naples early in November, and succeeded in cultivating what is believed to be a peculiar pathogenic organism from the blood of a young woman in the collapse stage of the disease. The blood was obtained about six hours before death from the median vein. The surface having been carefully washed with water, alcohol, and a 1 per cent. solution of corrosive sublimate, the vein was punctured, and the blood, which was observed to be thick, trickled slowly out. The first drops having been carefully got rid of, a previously heated platinum wire was passed into the vein, and on being withdrawn was then introduced into a test-tube containing solidified nutrient gelatine, and the latter was pricked in three places. Ten such tubes were inoculated in this manner, and it was afterwards found that organisms developed in three of them; the remaining seven tubes continued to be sterile.

The organisms thus cultivated were of one kind, of cylindrical form with rounded ends, and found either singly or in pairs (seldom with more segments than two); and the length of each microbe was about one and a half times that of the width. According to Cohn's classification, therefore, they are bacteria, and as regards form and size are very like those found in diphtheria, but are to be distinguished from the latter by the form presented by their "colonies" when grown in gelatine and examined under a low power. They grow at ordinary temperatures in slightly alkaline gelatine (which is liquefied) as solid opal-glass-like patches. Under a power of 100 diameters such of the colonies as develop in the deeper portions of the nutrient gelatine on the glass plate present the form of a hone, and those on the surface simulate flat, circular, mussel-shells. The deeper colonies are yellowish-brown by transmitted light, white by reflected light, and have a finely granular appearance. The more superficial colonies are pale-yellow towards the middle and whitish at the margin; and they manifest a tendency to spread over the surface as a thin transparent coating.

These organisms have not only been cultivated from the blood, but also from the internal organs of nine persons who had died of cholera. They were found to be most numerous in the kidneys and liver, then in the lungs, and least numerous in the spleen. Dr. Emmerich found that the greater number of the gelatine plates which were inoculated with the blood and with the juices of the several organs in cholera yielded, even in the first generation, a "pure culture" of this bacterium. The microbe has also been detected without resorting to cultivation in sections of the intestine and of

Digitized by Google

the kidney. Other organs have not as yet been examined. Great numbers may be detected in the dejections and in the intestinal contents after death. They were found to grow in every gelatine-plate cultivation of choleraic alvine material, and in some cases occupied almost the entire surface of the plate; whereas in other cases, though more seldom, comma-shaped bacilli prevailed, but never to the exclusion of the particular organisms in question.

The most important part of Dr. Emmerich's communication, however, refers to the inoculation experiments which he, in conjunction with Dr. Sehlen, made at the Hygienic Institute of Munich. The animals experimented upon were for the most part guinea-pigs, and it is believed that lesions have been induced in animals by inoculation with this bacterium which simulate those observed in persons who have died of cholera, and especially as regards the small intestine. The changes have been noticed to vary from a simple desquamative catarrh, with rice-water-like intestinal contents, to hæmorrhagic exudation and ulcerative destruction of the mucous coat. A couple of drops of a solution prepared by the addition of a fragment (about the size of a pin's head) of this bacterial cultivation to two or three drachms of distilled water, injected subcutaneously or into the lungs, give rise to a protracted illness of from five to six days, accompanied with deep-seated changes in the intestinal mucous membrane; whereas the injection of a larger fragment of the cultivation, covering, say, an area of about a quarter of an inch, suspended in water, is followed by death in from sixteen to thirty hours, but with less emphasised pathological lesions in the intestine; the severity of the intestinal lesions being thus the more marked the more protracted the course of the disease, and the larger the dose the earlier the fatal termination.

Several other matters of much interest in connexion with the subject of cholera causation are dealt with in Dr. Emmerich's paper; but the space at our disposal does not permit of our doing more at present than to bring before our readers the salient points of the evidence adduced in support of the specific characters and pathogenic properties of the apparently new cholera microbe to which he calls the notice of the profession.

Pharmacology and Therapeutics.

EULACHON OIL.

EULACHON OIL is advocated by Dr. Lyons of Detroit as a substitute for cod-liver oil. The bays and estuaries of the Pacific coast of British America and Alaska are annually visited by immense shoals of a small fish popularly known as the candle fish, eulachon, or outachon. This fish belongs to the family of the salmonidæ, and bears the scientific name of Thaleichthys pacificus. The candle fish is less than a foot in length. The spawning season is in April and the first half of May. The fish is chiefly prized on account of its oil, which is used as food by the Indians. So rich in oil is the entire fish that when dried it serves the natives for torches, whence its name. The commercial oil contains much palmitin, and probably stearin, so that at common temperature it is only semi-fluid. The olein, which for medicinal purposes at least must be regarded as eulachon oil, forms a limpid fluid of a pale-straw colour and fishy odour, unlike that of cod-liver oil, and is perhaps to many less repulsive. Its specific gravity is not very different from that of cod-liver oil, but it is rather more viscid. When mixed with sulphuric acid (five volumes of oil to one of acid) the temperature rose to 55° C., with cod-liver oil the elevation of temperature is about double this. The colour reactions with acids are very different from those of cod-liver oil. Sulphuric acid does not produce with eulachon oil the rich purple colour which obtains with cod-liver oil and other oils containing biliary ingredients; it produces a deep brown tint. The oil probably contains a trace of iodine. The fatty acids obtained after saponification amounted to 95·85 per cent. Eulachon oil contains about 13 per cent. of an unsaponifiable substance, which is the most peculiar and interesting constituent. The low specific gravity of this peculiar ingredient, and its indifference to most reagents, remind one strongly of the paraffins; and now that petroleum and petroleum oil are recognised as having a positive influence on tuberculous complaints, we shall not be surprised if eulachon oil be found to owe any therapeutic efficacy it may have to the presence of this peculiar body.

ASEPTOL.

This antiseptic agent, which is chemically known as orthoxyphenyl sulphurous acid, is a body belonging to the aromatic series, and is allied in chemical composition to salicylic acid; the comparison of the rational formulæ will show the resemblance and difference between the two bodies:

Aseptol ... ... $(C_6H_4OH)(SO_2OH)_2$.
Salicylic acid ... ... $(C_6H_4OH)(COOH)_2$.

Aseptol is an acid phenol, and it is the acid property it possesses which neutralises the ammoniacal bases which accompany the processes of putrefaction. Aseptol is a syrupy liquid of amber colour, and possesses a density of 1400. It has a faint characteristic odour, which is, however, disagreeable. It crystallises at 8° C., and boils at 130° C. With ferric chloride it shows a violet colour like that given by salicylic acid. Treated with potash it yields pyrocatechin, resorcin, and hydrochinon. A small dog, weighing seven kilogrammes, took by the mouth seven and a half grammes of aseptol without experiencing the least distress; carbolic acid in a dose three times as small produced violent convulsions and grave disturbances, followed by death. Aseptol is believed to be preferable to salicylic and phenic acids wherever an antiseptic agent is required—e.g., in cases of disease of mucous membranes, especially the conjunctiva.

NAPHTHALINE.

Dr. Rossbach has used naphthaline as an antiseptic agent with a view of checking diarrhœa, and, it is said, with excellent results. The medicament is believed to be efficacious in cases of intestinal catarrh, even when chronic, with or without structural alterations, provided the changes are not of a cancerous nature. The good effects are obtained after the use of the drug from five to ten days. The same remedy appears to be useful in cases of diarrhœa due to tubercular disease of the bowel. Naphthaline in small quantities escapes with the urine, and seems to have a beneficial influence on some diseased conditions of the mucous membrane of the bladder, such as vesical catarrh. After the lapse of a few days the microbes which abound in the alkaline urine disappear, the deposit of muco-pus diminishes, and the general condition participates in the amelioration. Naphthaline is nearly always well borne, the digestion is not disturbed, and small doses are said to improve the appetite. The exhibition of the drug may be continued for many months without causing inconvenience.

APOMORPHIA.

From an investigation into the action of apomorphia on some cases of epilepsy and chorea, M. Weill has come to the conclusion that this powerful agent may be beneficially employed in cases of nervous disturbance. The hydrochlorate is used in doses of from two to six milligrammes. All diseases associated with spasmodic action are relieved by it. Hiccough, epilepsy, and chorea have been much benefited thereby. A sedative action is produced without nausea or vomiting, provided the doses be as small as above mentioned.

"Audi alteram partem."

CHARCOT'S DISEASE.

To the Editor of THE LANCET.

SIR,—The recent discussion on Charcot's disease, and the interesting features it disclosed, naturally suggest the question whether the disease can be traced in the pathological researches of the insane, as, from its affiliation to neurotic disorders, one would suppose might be the case. Dr. Moxon seems to have implied something of the kind in his off-hand allusion to the prevalence of certain fractures among the inmates of asylums, and I venture to think the idea is worth pushing further. It has been frequently asserted that a morbid fragility of bone is sometimes detected in the insane, and I have myself seen the condition of the

Digitized by Google

ribs so altered as to admit of the bones being readily snapped between the finger and thumb in subjects undergoing post-mortem examination. We also know as a fact that fractures of ribs may occur without any history of violence, as the records of some asylums prove. It is undoubtedly a matter for serious regret that the immense fields of pathological research possessed by many of these institutions should be so inadequately cultivated. Judging from my own experience of one of the principal public asylums with which I was for some years connected, the opportunities of garnering valuable pathological knowledge is too lightly esteemed. I occasionally contributed a few more important specimens of disease to the Pathological Society and Hunterian Museum, but it was, to my mind, simply deplorable that so little in the way of cultivating a collection of specimens to elucidate particular forms of disease was ever attempted. The bare records of each autopsy was invariably entered in a book provided for the purpose, but beyond this nothing. Had the opportunity ever occurred, it had been my intention to have established a museum of pathology in that asylum, and I strongly suggest that by such means a greater impetus would be given to work of this important description. Indeed, scientific work in our public asylums, especially in connexion with the deadhouse, cannot be too urgently insisted on. While writing on this subject I should like to offer another suggestion—viz., that all the attendants be subjected to a system of special training, as nurses are in general hospitals. I do not know if under the present improved management such a system is carried out, but it is undoubtedly one of great importance, no less for the patients than for the attendants themselves, that they should be carefully trained and instructed in their duties. Apologising for the length of my communication,

I am, Sir, yours obediently,

J. HAWKES, M.D.

Queen's-park terrace, W., Dec. 22nd, 1884.

COCAINE AS A LOCAL ANÆSTHETIC.

To the Editor of THE LANCET.

SIR,—In spite of all that has lately been written about cocaine, we have probably much more to learn of the valuable properties of this drug as a local anæsthetic. Last evening I had occasion to recommend circumcision upon a patient, aged twenty-three, who had come to consult me in the surgery. Having explained to him the nature of the new drug, he readily consented to give it a trial. A 4 per cent. solution of the hydrochlorate of cocaine was made in distilled water, and of this 4 minims were injected through the foreskin at four different points—one on the dorsum, one near the frænum, and one on either side—altogether sixteen minims. In about twelve minutes anæsthesia was complete all round, and with the assistance of Mr. R. B. Hughes, of University College, the operation was performed, the patient watching the proceedings with considerable interest, and being greatly surprised at feeling no pain whatever after the pricking of the needle for the hypodermic injection. It will be observed that rather a large quantity was injected, yet, so far as we could make out, no constitutional effects whatever were produced upon the patient, and the local effects lasted long enough for the man to walk home and go to sleep without feeling any pain. This morning, however, he tells me that he awoke twice in the night with pain. I have never before performed this operation without chloroform, the administration of which must always involve some risk and a very considerable amount of trouble.—I am, Sir, yours faithfully,

OWEN PRITCHARD, M.D.

Southwick-st., Hyde-park, W., Dec. 23rd, 1884.

To the Editor of THE LANCET.

SIR,—I was consulted this morning by a patient suffering from the various symptoms of stricture of the urethra. The urethra was in this instance so very sensitive, and the patient so nervous, that I found it quite impossible to make a satisfactory exploration. Having by me a 4 per cent. solution of a new sample of muriate of cocaine, just manufactured by Corbyn and Co., I injected half a drachm, and retained it within the urethra for five minutes. I found that I could now pass a metal bulb almost without pain, and easily made out a stricture of 17 millimetres circumference, in a urethra of 30 millimetres normal calibre, at a distance of 4 centimetres from the meatus. I now attempted to make a more complete examination with the urethrometer, but found that the urethra beyond the stricture was still very sensitive. I injected some more solution of cocaine, and this time caused it to be retained nearly half an hour. Finding that I could apparently now perform any manipulation upon the urethra without pain, and not finding a deeper stricture, I determined to operate at once, and divided the stricture with my modification of Otis' urethrotome up to the normal calibre of the urethra. The patient informed me that the operation was almost entirely painless. As patients generally complain of a good deal of pain while the instrument is being screwed up to put the stricture tissue on the stretch, the absence of it upon this occasion is more worthy of note. Of course definite conclusions cannot be arrived at by the result of one case, but the prospect seems very promising. If the observations of other medical men and my own future experience shall be found to coincide with the result of this case, I think we shall find that operations upon the urethra will be greatly facilitated by the use of this drug. By dispensing with a general anæsthesia, we render the patient able to assist the operator by his intelligent co-operation. I am of opinion that it will be found that the passage of the large instruments and evacuating tubes used in our modern operation of lithotrity can be rendered entirely painless by a preliminary injection of this drug, and the treatment of irritable stricture by dilatation robbed of more than half its terrors.

Yours faithfully,

GEORGE HERSCHELL, M.D. Lond.

Moorgate-street, E.C., Dec. 20th, 1884.

LIVERPOOL.

(From our own Correspondent.)

CHRISTMAS CHARITIES.

THERE seems every prospect that in this city the wishes expressed in last week's issue of THE LANCET will, to a very considerable extent, be realised. Our present mayor, Alderman David Radcliffe, has originated the happy idea of presenting 1000 "hot pots" to the poor on Christmas Day. They are to be distributed through clergy, priests, and ministers well acquainted with the poorer classes. Each "hot pot" is to contain 10 lb. of meat and potatoes, to be accompanied by a large loaf of bread, and to be supplied by a well-known firm, whose name is sufficient guarantee of the excellence of their quality. As might have been expected, such munificent generosity has proved contagious. Another gentleman has promised 500 "hot pots" to the deserving poor of St. Jude's district, to be distributed through its present incumbent in charge. A third generous donor promises a quart of best ale to each holder of a ticket for the mayor's bounty. A fourth has promised to distribute 1000 ¼ lb. packets of good tea. It is possible that in the interval between now and Thursday further generous donations may be announced. For many years past Christmas breakfasts have been provided to a number of the deserving poor, and this is to be repeated on Thursday. Hence, for at least that day, starvation will be forgotten by many, and a large number of the hungry will be filled with good things. Judging also by past experience and present appearances the poor in all the local hospitals will be well cared for, and their Christmas be made happy, if it cannot be made merry.

DEATHS OF LOCAL MEDICAL PRACTITIONERS.

Many old associates of King's College will learn with deep regret of the death of Mr. George Henry Snape, which occurred on the 13th inst., after a long and painful illness, at the early age of forty. The deceased was the second son of Mr. Joseph Snape, who still lives and enjoys excellent health, and who formerly enjoyed a large practice as a dentist, first in Chester, then in Liverpool. He was joined by the deceased about sixteen years ago, and on the retirement of the former some years ago the whole of the practice was carried on by the deceased, aided by competent assistants. His death is sincerely lamented by a large circle of friends, professional and general, to whom he had greatly endeared himself by his amiable temper and genial manners. The deaths are also announced of Mr. Arthur Prince May, surgeon, of Crosby;

Digitized by Google

of Dr. Crichton, of Walton-on-the-Hill; and of Dr. Adolphus Frederick Graham. This last occurred under very sad circumstances. The deceased, who was forty-eight years of age, and formerly enjoyed considerable reputation as a successful ovariotomist, had been lately in failing health, and was much depressed in spirits. On Saturday last he committed suicide by cutting his throat, dying soon after being found. He had practised in Liverpool for twenty-two years.

Liverpool, Dec. 22nd.

BIRMINGHAM.

(From our own Correspondent.)

HOSPITAL OUT-PATIENT REFORM.

IT is interesting to notice in what a variety of modes public opinion is formed on certain subjects, and how gradually but surely the different details tend ultimately to the same focus. At the Birmingham Debating Society a discussion lately took place upon the above question. The motion being that "the out-patient department of hospitals and the public dispensaries (casualties excepted), as at present administered, do more harm than good." Some animated speeches were made on both sides, and much interest displayed in the numerous facts quoted. The result was a large majority for the affirmative. Doubtless the knowledge gained at this meeting will be utilised in the right direction when time has ripened this important matter for more immediate action.

HEALTH LECTURES.

The second series of Public Lectures on Health has been again remarkably well attended. Last week the subject taken by Dr. Malins was "Health and Education," in which exercise was made the fundamental note in the use of the mind, the body, and the moral sentiments. Allusion was made to the vexed question of over-pressure, and the consequences of it forcibly pointed out. On Tuesday the last of the series was given by Mr. Chavasse, to men only, entitled "Practical Hints on Personal Health." Popular ignorance on many subjects was pointed out, and the evils of quacks especially exposed and denounced in an able and eloquent manner.

MEDICAL CERTIFICATES OF DEATH.

The coroner for the borough has replied to some facts which have been made prominent in the daily papers in reference to the giving of death certificates in cases where the patient has not been seen for some time previously by the medical attendant. With regard to the practical application of the law, the certificate itself in its wording affords sufficient latitude, being framed in such a manner that the information as to death may be given as direct or indirect.

PENNY DINNERS.

By the efforts of a philanthropic lady the first start was made a few days ago in providing cheap dinners for the poorest children of certain districts. About two hundred were furnished with penny tickets at various schools, and at the appointed time each child had the choice between a pint of savoury soup with four ounces of bread, or a plate of about twelve ounces of peas pudding. The soup was composed of lentils, onions, carrots, pearl barley, flour, and beef bones, and was evidently much appreciated. The dinner was decidedly a success. A plan for variety in the composition and flavour of the soup will give a pleasant change from time to time. The penny it is calculated will defray not only the cost of the food supplied, but will also cover the expense involved in the use of the rooms and wages of the attendants. Other committees have been formed in different parts of the town in connexion with elementary schools, and the experiment is looked forward to in the winter months with enthusiasm and as one likely to be successful.

DONATION.—The Medical Staff of the Mater Misericordiæ Hospital, Dublin, have given £100 towards the funds of that institution.

THE Kingston Town Council have decided to promote a Bill in Parliament for the dissolution of the Lower Thames Valley Main Sewerage Board.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

ORAL TEACHING OF THE DEAF AND DUMB.

MR. B. ST. JOHN ACKERS, of Painswick, Gloucestershire, recently delivered a most interesting lecture on the above subject. The lecturer commenced his address by referring to the various causes of deafness, and described the two present systems of educating the deaf and dumb, known as the French or sign system, and the German or modern pure oral system. He claimed for the latter all possible advantages, and scarcely had a good word to say for the French or sign system. He stated further that those congenitally deaf educated under the French system "seldom rose in life," a statement that was scarcely in accordance with the experience of some of his hearers. In short, Mr. Ackers is evidently an enthusiast as regards the German system; but in the discussion following his lecture the true position of the oral system was assigned, by some speakers who had experience in teaching deaf mutes, to selected cases where a knowledge of language had been originally possessed, and afterwards lost through deafness. There can be no doubt that it is most desirable to keep up speech when it can be at all accomplished, and so in such cases the German system is certainly preferable. The German system is not altogether new after all, for we know down here that, according to the Venerable Bede of Jarrow, John Bishop of Hexham taught a deaf-mute man to speak and repeat sentences; and it is also on record by the same writer that John de Beverley, Archbishop of York, taught two deaf and dumb men to speak. These events are recorded as taking place in the sixth century.

SMALL-POX IN DURHAM.

The reports of the small-pox epidemic as regards the city of Durham point to a steady decrease; in some of the surrounding villages, however, the disease would appear to have taken a somewhat firm hold; in the village of Langley Moor, a short distance from Durham; the medical officer of health reports twenty cases.

THE MILK-SUPPLY QUESTION.

The *Newcastle Chronicle* gives an interesting account of a successful endeavour of the workpeople at one of our Northumbrian collieries to supply themselves with new milk on the co-operative system. North Seaton is the name of the place where the experiment has been tried. The workpeople clubbed together and established a dairy. The first attempt was on a small scale, with only three cows; but after one or two failures from loss of cows the farm is now firmly established with a stock of fourteen animals, and after twelve years' operations it must, besides supplying the want for which it was originated, be regarded as a commercial success, for the last half-yearly report shows that, after paying all expenses and setting up a reserve fund to meet accidents and losses of animals as well as deterioration of stock, there remained for the members a dividend of 10 per cent.

PERMANENT OR TEMPORARY HOSPITALS FOR INFECTIOUS DISEASES.

In view of the spread of small-pox in the county of Durham, the sanitary authorities of the various boards are much interested in the question as to whether it is better to make use of a temporary building or erect a permanent hospital. Much is to be advanced on both sides; but the economists in one of our unions "scored a point" when they pointed out that a temporary hospital of wood and patent felt, as now manufactured at Copenhagen, would not cost more than £500 to erect, with all its fittings; the board, however, very prudently deputed a committee to visit one of these hospitals, which is at present in operation at King's Norton, near Birmingham, and report upon it.

THE EXTENSION OF THE NEWCASTLE INFIRMARY.

The proposed extension of the Newcastle Infirmary, at a probable cost of £13,000, is the subject of conversation in medical circles here, and it is well-known that some of the medical staff are very strongly opposed to the project, and would regard any permanent extension of the house on its present objectionable site as "a blunder." I shall refer to the matter again in a future letter.

TYPHUS AT SUNDERLAND.

At a late meeting of the Sunderland Board of Guardians the master reported that in the previous fortnight five cases of typhus fever had been admitted into the hospital, and one case discharged, leaving nine cases under treatment.

THE NEWCASTLE MEDICAL OFFICER OF HEALTH'S REPORT.

At the City Council meeting to-day the report of our medical officer was adopted, and spoken of in the highest terms as displaying on the part of Mr. H. E. Armstrong much ability and zeal in the performance of his duty.

Newcastle-upon-Tyne, Dec. 17th.

THE SERVICES.

Deputy Surgeon-General J. G. Faught, who was appointed to the Staff of Major-General F. A. Willis, C.B., Northern District, a short time ago, has been appointed principal medical officer at the Cape of Good Hope.

ARTILLERY VOLUNTEERS.—The Tynemouth: Surgeon Frank Rennie, M.D., resigns his commission; Acting Surgeon William Pope Mears, M.D., to be Surgeon.

RIFLE VOLUNTEERS.—1st Battalion of the Gordon Highlanders: Surgeon Angus Fraser, M.D., is granted the honorary rank of Surgeon-Major.—1st Battalion of the Lancashire Fusiliers: Acting Surgeon Jonathan Edward Lees, M.B., to be Surgeon.

Obituary.

HENRY MUSCROFT, M.D. ST. AND.

DR. HENRY MUSCROFT died on Dec. 5th, 1884, from disease of the heart (dilatation of the left ventricle, &c.), from which he had suffered in a marked degree for the last two or three years.

Dr. Henry Muscroft was born on the 7th of March, 1830, and was the fourth son of the late Dr. James Muscroft of Pontefract. He studied medicine at the Leeds School, and became M.R.C.S. in 1854 and L.R.C.P. in 1862, and M.D. St. And. in 1871. He was placed on the Commission of the Peace in 1872. Amongst the appointments he held were House Surgeon to the Leeds Infirmary and to the Scarborough Dispensary; Medical Officer for the Pontefract Union Workhouse, and for No. 1 District Rural Sanitary Authority; Medical Officer of Health for Pontefract; Factory Surgeon; Surgeon to the Police, and Consulting Physician to the Pontefract General Dispensary. He was surgeon to the 1st West York Militia (now 3rd Battalion South Yorkshire Regiment) from its embodiment nearly thirty years ago, during which time he saw five years' embodied service in England, Ireland, and Scotland. From 1879 up to his recent illness he had charge of the Pontefract Brigade Depôt, being one of the few militia surgeons who were given charge of regular troops.

On March 1st, 1870, he married the youngest daughter of the late Rev. Dr. Bisset of Bourtie, Aberdeenshire, and niece of the Rev. Dr. Bisset, formerly Vicar of Pontefract. He leaves four children, three boys and, the youngest, a girl.

It is only those who were thrown in contact with Dr. Muscroft in his professional capacity who can fully realise the causes which so endeared him to all. He took with him to the bedside of the poorest the same tenderness, sympathy, and anxiety for their welfare that he showed in the treatment of those most dear to him. It may readily be believed that in a man of his anxious temperament a continuance in the exercise of his profession was not to be desired once the disease from which he suffered had fully declared itself. But situated as he was, with a young family dependent in great measure on his exertions, he did not think it his duty to relinquish work. And how far he thought his duty took him may be shown in the following instance. A few days before he finally had to give up work an accident happened to a man who was taken to the Workhouse Hospital. Though extremely ill, and though some of his medical friends would gladly have relieved him of the labour, he left his house at night to attend the case himself. He had frequently to rest on his way, attacks of dyspnœa being very urgent, and remained in attendance on the case for two hours. This may be said to have been his last effort. On the return of his partner from his holiday Dr. Muscroft gave up work, and after an illness of fifteen weeks, borne with that patience and cheerfulness which distinguished him, he died on December 5th, and Pontefract lost one who, it may fairly be said, cannot be replaced; one who in his too short life never made an enemy, and who always found the best thing possible to be said about others.

The funeral took place on December 9th, and was attended by the mayor, corporation, and borough officials, as well as by the staff sergeants of his old regiment, by volunteers from the depôt, by many of the officers quartered there, and by numerous private friends. But that which was the most striking sight was the great number of the working classes, many of whom had hurried from their work and devoted their dinner hour to paying their last tribute to one they so much respected and esteemed. At the cemetery it seemed as if each one present had lost a dear and treasured friend.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on the 18th inst.:—

Armstrong, Leonard H., Newcastle-upon-Tyne College of Medicine
Barnett, Lawrence, University College.
Bradbury, Harvey, London Hospital.
Gaston, Harry Percival, Charing-cross Hospital.
Going, Joseph Andrew, London Hospital.
Good, John, Charing-cross Hospital.
Hazell, Robert William, London Hospital.
Harries, John Frail, King's College Hospital.
Meller, Charles Booth, M.R.C.S., L.R.C.P., St. Bart.'s Hosp.
Morris, Collier Dwight, London Hospital.
Phillips, Wm. Edw. Picton, Guy's Hospital.
Reece, Richard James, St. Bartholomew's Hospital.
Wild, Robert Briggs, Owens College, Manchester.
Volckman, Bernard, London Hospital.

THE "CEYLON."—We understand that this pleasure steam yacht will start from Gravesend on Jan. 24th next, for a sixty-five days' cruise. The office is at 7, Pall-mall, S.W.

AT a meeting held at Henley on the 18th inst., a committee was appointed to consider a scheme for the establishment of an infectious diseases hospital for Henley and neighbourhood.

THE International Society for the Prevention of Blindness and the Amelioration of the Condition of the Blind has adjudged to Dr. Mules, Surgeon to the Manchester Royal Eye Hospital, one of two prizes offered for an essay on the "Causes and Prevention of Blindness."

DISUSED BURIAL-PLACES AS RECREATION-GROUNDS.—The Consistory Court of London has decreed that a faculty should issue to convert the disused burial-ground of West Hackney into a recreation-ground for the use of the parish.

AUSTRALASIAN SANITARY CONFERENCE.—The first meeting of this conference was held at Sydney on Sept. 17th. Various matters important to the colony were discussed, and a series of resolutions defining the scope of the body and the regulations which are to guide it were adopted.

AT an inquest held at Islington on the 18th inst., by Dr. Danford Thomas, on the body of Mr. John Barrow, Surgeon, who died from the effects of morphia which he had taken in the form of pills for the relief of sleeplessness, the jury returned a verdict of "Death from misadventure."

A PARISIAN jeweller has been fined fifty francs for homicide through imprudence, and ordered to pay 150 francs damages to the parents of a child whose death he had caused by piercing its ears for earrings too high up, the operation having been followed by inflammation.

DEATH FROM CHLOROFORM.—At an inquest on the 16th inst., at the Royal Surrey County Hospital, relative to the death of a man in that institution while under the influence an anæsthetic, the jury returned a verdict of death by misadventure through the administration of choloform.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BOOBBYER, PHILIP, M.R.C.S., has been appointed Medical Officer of Health to the Basford Rural Sanitary Authority, vice Buckby, resigned.

CLUBBE, WM. HENCHMAN, M.R.C.S., L.S.A.Lond., has been appointed Consulting Surgeon to the Lowestoft Hospital.

EWART, C. THEODORE, M.B., M.Ch.Aberd., has been appointed Assistant Medical Officer to Leavesden Asylum, vice Lloyd Francis, M.B.Oxon., M.R.C.S., resigned.

HEYGATE, W. N., M.R.C.S., L.S.A.Lond., has been appointed Surgeon to the Central or City District of the Bath Friendly Society, vice H. C. Hopkins, resigned.

KEALY, JOS. PATRICK, L.K.Q.C.P.I., L.R.C.S., has been appointed Medical Officer to the Hillstone Hospital, New South Wales; also Government Medical Officer and Public Vaccinator at Hillstone.

MACKENZIE, JOHN HUGH, F.R.C.S.Ed., has been appointed Government Medical Officer and Vaccinator for the District of Temora, New South Wales.

MASKEW, JOHN SHEPPARD, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for part of the Third District of the New Forest Union.

MASTERTON, JOHN, M.B., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Second District of the Alston-with-Garrigill, Parish, vice Jefferies, resigned.

MURRAY, H. MONTAGUE, M.D., M.R.C.P., has been appointed Assistant-Physician to, and Lecturer on Practical Medicine at, the Charing-cross Hospital.

RAY, JAMES, M.R.C.S., L.S.A.Lond., has been appointed Surgeon to the Lowestoft Hospital, vice Clubbe, resigned.

RICHARDSON, FRANK L. C., L.R.C.P., L.R.C.S.Ed., has been appointed Medical Officer to the Rhayder District and Workhouse, Rhayder Union, vice R. Richardson.

SALMON, ARTHUR GUY, M.B., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Fifth District of the Bodmin Union, vice Couch, deceased.

THURSTAN, Dr. HUGH C., has been appointed Resident Medical Officer to the Bristol Royal Infirmary.

WHITCOMBE, P. PERCIVAL, M.R.C.S., L.S.A.Lond., has been appointed Resident Obstetric Officer to St. Mary's Hospital, London.

Births, Marriages, and Deaths.

BIRTHS.

CLARE.—On the 19th ult., at Sutton's Pasture, Vere, Jamaica, the wife of Henry L. Clare, M.B., District Medical Officer, of a daughter.

STEVENSON.—On the 20th inst., at Camberwell-grove, Denmark-hill, the wife of Leader Stevenson, M.D., of a daughter.

THOMSON.—On the 18th inst., at Sinclair-road, West Kensington-park, W., the wife of G. Crawford Thomson, M.B., M.R.C.S., of a daughter.

MARRIAGES.

BUXTON—CLARKE.—On the 18th inst., at All Saints', Odiham, Hants, by the Rev. T. G. Clarke, M.A., Vicar of Odiham, father of the bride, assisted by the Rev. H. I. Wilmot Buxton, M.A., Vicar of St. Giles's in the Wood, Torrington, brother of the bridegroom, and the Rev. Prebendary Stephenson, M.A., Rector of Lympsham, and the Rev. W. Clarke, M.A., Vicar of Hook. Dudley Wilmot Buxton, M.D., M.R.C.P., son of the late Harry Wilmot Buxton, Esq., Barrister-at-Law, to Louisa Frances Agnes.

LOVELL—TICKLE.—On the 30th Oct., at the Cathedral, Sydney, N.S.W., Robert Haynes Lovell, L.R.C.P.Lond., M.R.C.S., eldest son of Major R. Haynes Lovell, of Barnstaple, N. Devon, to Florence Mary, daughter of J. B. Tickle, Esq., of Sydney.

STEELE—JOHNSTONE.—On the 17th inst., at the Church of St. Michael and All Angels, Bedford park, by the Rev. A. Wilson, M.A., Warwick Charles Steele, M.R.C.P., M.R.C.S., second son of Edward Steele, Esq., J.P., Wollaston House, Dorchester, to Eliza (Lizzie) Julia, fourth daughter of the late Robert Johnstone, Esq., M.D., of Trinidad.

TEEVAN—HALL.—On the 4th inst., at Trinity Church, Rathmines, Dublin, Thomas Teevan, Deputy Surgeon-General, to Elizabeth Jane, only child of the late Edward Hall, Esq.

WOMACK—CHRISTMAS.—On the 18th inst., at St. Mary's, Kilburn, Frederick Womack, M.B., B.Sc.Lond., second son of Jas. Womack, of Abbey-road, N.W., to Ada, only daughter of Walter Christmas, of Mowbray-road, Brondesbury, N.W.

DEATHS.

AYLING.—On the 19th inst., at his son's residence, 94A, Great Portland-street, Portland-place, W., William Henry Ayling, L.R.C.P.E., M.R.C.S.E., and L.S.A.Lond., aged 67.

BARROW.—On the 14th inst., suddenly, at 219, Tufnell-park-road, John Barrow, M.R.C.S., L.S.A.Lond., eldest son of the late Rev. John Barrow, aged 33.

DALBY.—On the 19th inst., at his residence, Belvedere House, Torquay, William Bennett Dalby, M.D., F.R.C.S.Ed., &c., aged 60.

LACY.—On the 18th inst., at his residence, Saumarez Lodge, Guernsey, Thomas Saumarez Lacy, Deputy Inspector-General of Hospitals, H.M. Indian Army (Retired), and for many years Garrison Surgeon at Agra, aged 68.

MAY.—On the 18th inst., at Great Crosby, A. P. May, M.R.C.S., aged 62.

TEBAY.—On the 20th inst., very suddenly, Thomas George Tebay, M.D., of 37, Belgrave-road, S.W., aged 69. R.I.P.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE EXTINCTION OF CHOLERA EPIDEMICS IN FORT WILLIAM.

THE insertion of Deputy Surgeon-General Marston's communication on the above subject is unavoidably postponed until next week.

Mr. Lewis Bishop.—We do not prescribe.

Mr. Greig-Smith's paper will appear in an early number.

"SCOTCH MEDICAL EDUCATION AND EXAMINATIONS."

To the Editor of THE LANCET.

SIR,—Will you grant me the space these few lines will occupy to enable me to correct a misstatement which appeared in the letter of Mr. E. K. Campbell, in your issue of Dec. 13th, under the above heading.

With commendable filial affection, Mr. Campbell lauds the glorious *alma mater* which gave him professional birth; but in the excess of his devotion at his particular shrine he scarcely does justice to the sister university of Aberdeen, though certainly not thereby impairing the force of his argument in the case of Scotch *v.* English schools. In Aberdeen we now enjoy the privilege of a separate paper in Pathology in the Final M.B., and, moreover, we may be said, strictly speaking, to possess the only Pathological Chair in the kingdom; for though Edinburgh must always be accorded the credit of being the pioneer in this most important by way of the *via medica*, yet her advantage only extends to the length of a lectureship, while our "Erasmus Wilson" Chair demands the sole and undivided attention of the Professor. And perhaps the fact that the same wise restriction from the distractions of private and hospital practice applies in the several cases of the professors of botany, natural history, physiology, anatomy, and chemistry (subjects which are the very foundation-stones of the truly scientific structure), entailing, as it does, closer personal supervision of the men's work by the most competent guide, and more opportunity for the practical "laboratory" exercise on which we northmen pride ourselves. I say this condition is not the least important of the factors which go to place Scotch university education in the foremost position we are pleased to believe it occupies. No one, not even the most infatuated and clannish of Scots, believes that we have a monopoly of perfection as regards either our mode of education or our method of examination; but those of us who have any knowledge of how these things are managed by the English corporations have certainly a strong prejudice against being reformed on their lines.—I am, Sir, yours truly,

Yeovil, Dec. 15th, 1884. A. ERNEST ROBERTS, M.B. Aberd.

To the Editor of THE LANCET.

SIR,—Looking over the correspondence in your issue of Dec. 13th, I was greatly surprised to read the statement made by Mr. E. K. Campbell, M.B.Ed., M.R.C.S. For his information, and to correct the erroneous impression he may have given to many of your readers, I beg to state that the University of Glasgow for many years has set a special paper in Pathology, and also holds an examination in Practical Pathology, whereby each candidate is required to mount and describe two pathological specimens. From this it is plain that the Edinburgh University is not the only examining board that now sets a special paper on Pathology, as stated by your correspondent.—Yours truly,

Glasgow, Dec. 16th, 1884. DAVID MOFFAT, M.C.S., C.M.Glas.

To the Editor of THE LANCET.

SIR,—Referring to Mr. E. K. Campbell's letter in your issue of to-day, I beg to state, as a graduate of Glasgow University, that he is wrong in supposing that Edinburgh University is the *only* examining body that sets a separate paper on Pathology. We have a separate written examination in Pathology at Glasgow, and a special oral examination, together with microscopical and naked-eye examinations of pathological specimens. I am, Sir, yours faithfully,

Guilford-street, W.C., Dec. 13th, 1884. ALEX. HOWIE.

Senex.—We are certainly of opinion that the distribution by book-post without special precautions of pamphlets on so delicate and difficult a question is, however well meant, to be condemned.

Dr. H. Neale is thanked.

N. E. D.—The lines are scarcely suitable for our columns.

COCAINE IN DIPSOMANIA.

T. G. T. is referred to an article by Freud, published in the "Centralblatt für Therapie," Wien, July, 1884. The article has also appeared in a separate form.

Chirurgeon is referred to our advertising columns for the information he desires.

SANITATION IN THE BEDROOM.

To the Editor of THE LANCET.

SIR,—Beds are occupied night after night, year after year, by divers persons in sickness and in health, in summer's heat and winter's cold, and as to when bedding is remade and purified each one can judge by his own experience? Compare this with the use of the South American hammock, which only requires a stout blanket inside, and in winter a woollen sleeping dress as well of suitable make—*i.e.* drawers, socks, and a loose jacket, all periodically washable. The sanitary difference becomes at once startling to those who have never considered the subject before. The South American hammock is made of the fibres of the young leaves of the ita palm (*Mauritia flexuosa*), so woven that it yields to every movement and projection of the body in every direction, except lengthways, in which direction the weight of the body establishes its own support, the same as in chairs with the loose canvas backs. Hammocks are very easy to get into and out of, and one cannot fall out of them when asleep. They should be swung the same distance from the ground as the seat of a chair. They form an excellent seat. Sitting down, one draws the back of the hammock up as high as one may desire. The proper way to get into a hammock—for there is a proper way—is first to sit down on it, and then throw the legs up and the back down, wrapping yourself up in its soft, elastic, and ample folds. The best way to lie is crossways. The position can be varied in three or four ways. The writer has passed several nights in such a hammock and blanket, exposed to the damps of a South American forest, and risen perhaps more refreshed than if he had slept in a bed. For bed-ridden people their use would be invaluable. Those who have been confined to a bed or water-bed for three or four months know how fatiguing and disgusting they become. In many cases in hospitals such hammocks would be real sanitary appliances. The hammock I have comes from the Essequibo Indians in British Guiana. I do not know why a similar mode of open weaving (more like knitting without the knots) of some material having the mellow feeling of the rush used in rush-bottomed chairs could not be managed in this country.

I am, Sir, your obedient servant,

Dec. 8th, 1884. TRAVELLER.

CASSAN *v.* FYFE.

To the Editor of THE LANCET.

SIR,—I enclose a copy of a resolution passed at the annual meeting of the Lincoln Medical Society, held on the 19th inst., when the above case was brought forward.—I am, Sir, yours truly,

Dec. 22nd, 1884. W. A. CARLINE, M.D., Hon. Sec.

"That the Secretary be requested to convey to Mr. Cassan the sympathy of this meeting with him in reference to the late trial at the Lincoln Assizes, and to inform him that a sum of £10 was unanimously voted towards defraying his legal expenses."

THE CASE OF DAVID BRADLEY, M.D.

WILL the correspondent who forwards a circular respecting the above kindly furnish us with his name and a report of the case?

STRANGULATED HERNIA IN AN INFANT THREE WEEKS OLD.

To the Editor of THE LANCET.

SIR,—The following case may be worthy of a place in your columns.

On Sept. 22nd, 1884, I visited a child three weeks old, for whom I had prescribed for symptoms of what the father described as "spasms." The child had been in great pain all night, and had been vomiting frequently; the abdomen was immensely distended with flatulence, and the child was evidently very ill; the skin of the face was pinched and shrunken. Over the right external inguinal ring, and into the scrotum, was a very evident hernial swelling, which, the parents said, was not present the previous day. Chloroform was given, and taxis fairly tried, but with no effect upon the hernia. I therefore arranged to operate as soon as possible, which I accordingly did the same evening, when, after thorough insensibility was produced, taxis was again tried, both by myself and my friend Mr. Arthur Shipton, whose valuable co-operation I had throughout; but we failed to produce reduction. On cutting down upon the tumour a very tightly strangulated direct inguinal hernia was brought into view. Reduction was impossible without opening the sac. The constricted portion of bowel was very dark plum-coloured, and formed a loop of about four inches in length. The division of the stricture was by no means easy, owing to the minute size of the tissues rendering it impossible to make good use of the finger in finding the stricture. However, with time and great care a director was passed under the constricting edge, and the stricture divided. Even then reduction was not at all easy, and the appearance of the bowel so tightly bent round on itself renders it easy to imagine that reduction without operation was out of the question. The further progress of the case was very gratifying. The sickness ceased, the bowels acted naturally the following day, and the child to-day (Nov. 11th) is looking extremely well. I would strongly advise any surgeon having a case of a similar nature to select daylight for operating. A similar case was related in THE LANCET of May 31st, 1884, by Dr. Dobbin, Bambridge, Co. Down. I am, Sir, yours truly,

Buxton, Nov. 11th, 1884. A. HASLEWOOD.

Digitized by Google

Dr C. W. C. Madden-Medlicott.—We regret that we cannot publish our correspondent's able and interesting letter. Touching, as it does, on a very delicate phase of the subject, it would probably provoke an amount of correspondence and discussion for which we could not possibly find room.

Madame Belloc.—We think the best course would be to advertise.

INTESTINAL OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—In common with no doubt most of your readers I have been much interested in the discussion on intestinal obstruction which lately took place at Liverpool. Reading the discussion reminds me of a case I attended in my practice three years ago. I have unfortunately mislaid the notes I then took; but the salient features of the case are distinctly present to me. It was the case of a woman fifty-eight years of age. When called to her she had pain, some tenderness, and slight swelling of the abdomen; there had been no motion of the bowels for four days previously. I commenced treatment by ordering poultices, rubbing the abdomen with belladonna ointment, and giving subcutaneous injections of atropine with soap enemata each night. This made no impression. I then ventured to give pills composed of two grains of subchloride of mercury with extract of hyoscyamine and soap. It was of no avail; the distension increased, and the prostration became very considerable. Morphia was given to allay pain, and ice to stop the almost incessant vomiting. This treatment, with some variation, was continued for twenty-eight days, and still there was no relief, the bowels remaining obdurate. By this time the distension was much increased, and the condition of the patient became very serious. To relieve the flatulence I punctured the bowel with a No. 1 trocar, and a few hours afterwards administered an enema of turpentine and castor oil. A slight quantity of fæces came away at the time, and on repeating the injection a copious evacuation took place, much to my delight. At intervals of a few hours several stools ensued, and a fortnight afterwards I had the gratification of seeing the patient walking about. But alas! for human hopes, about ten days after she had a relapse, through I believe some indiscretion in diet, and in the next ten days she sank from exhaustion, with all the appearance and symptoms of blood-poisoning from the absorption of morbid material from the bowels. I had not the opportunity of making an autopsy, I regret to say; but my experience has convinced me of the importance of puncturing the bowel in such cases, a point referred to by Dr. Rich. Another feature in the case is the length of time that may elapse without the issue being necessarily fatal. I may further refer to the tolerance of the alkaloid atropine, the doses I gave being much beyond the recognised limits of safety. I am, Sir, yours faithfully,

Nottingham, Dec. 22nd, 1884. COLIN MACMILLAN.

COMMUNICATIONS, LETTERS, &c., have been received from—Lady John Manners; Mr. Callander, London; Mr. Miller, Newport; Dr. G. M. Sternberg, Baltimore; Dr. Maunsell, Bath; Dr. Timothy Lewis, Bywood; Madame Belloc, London; Dr. Silvester, London; Mr. J. Abbott, Exeter; Dr. Laffan, Cashel; Mr. J. W. Pratt, Wiveliscombe; Mr. Douglas, Perth; Mr. W. A. Edgar, Dartford; Mr. Macmillan, Nottingham; Dr. Herschell, London; Dr. Lucas, London; Mr. R. Margerison, London; Dr. Finlayson, Glasgow; Mr. N. E. Micro-organisms and disease, 704
Microscopic objectives, 667, 855, 897, 948
Middlesex Hospital, 1119; introductory lecture by Dr. D. W. Finlay, 598; H.R.H. Princess Christian at the, 1112
Midget, the death of a, 379
Midwifery, 90; ergot and quinine in, 133; the want of practical teaching in, 943, 984
Migraine and tabes, 700
Mile-end Old Town, zymotic disease in, 1113
Military hygiene, 1061
Milk as a vehicle of disease, 793
Miller, Dr. J. W. Moore, obituary notice of, 173; the late, 440
—— Memorial Hospital, the, 1060
Milligan, Mr. K. W., the Evolution of Morbid Germs (review), 66; on prickly heat, 264; on the library of the College of Surgeons, 941
Minim, what is a? 441, 523
Minister of Health, a, 556

MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

ARGOATS HOSPITAL, MANCHESTER.—Fracture with dislocation of the astragalus; death from pneumonia; description of foot, 591
ASHBURTON AND BUCKFASTLEIGH COTTAGE HOSPITAL.—Dislocation of hip-joint in a boy; reduction five weeks after injury, 637
BRADFORD INFIRMARY.—Two cases of double colorectomy, 1091
CALCUTTA MEDICAL COLLEGE HOSPITAL.—Cases of aneurysm, 16
CHESTER GENERAL INFIRMARY.—Abscess of kidney; aspiration of forty-two ounces of pus; complete recovery, 61
CITY OF LONDON INFIRMARY, BOW.—Aneurysm of the left side of the abdominal aorta bursting into the bladder and simulating an affection of the cæcum, 870
COLONIAL HOSPITAL, SAN FERNANDO, TRINIDAD.—Imperforate rectum; cure, 776
CUMBERLAND INFIRMARY, CARLISLE.—Large irreducible umbilical epiplocele; removal of omentum, sac, and redundant skin; wood-wool dressing; recovery, 368—Pyo-salpinx; leakage into the uterine cavity; abdominal section; drainage; recovery, 493
DEVONSHIRE HOSPITAL, BUXTON.—Hereditary congenital malformation of hands and feet, 733
DUNDEE ROYAL INFIRMARY.—Acute chorea; extreme degree of jerking; administration of conium juice; recovery, 959
GENERAL LYING-IN HOSPITAL, YORK-ROAD.—Gestation; accidental hæmorrhage; death of fœtus in utero; arrested labour from rigor mortis of fœtus, 60
GUY'S HOSPITAL.—Fracture and dislocation of the cervical spine, 14—Conical cornea of both eyes, 144—Two cases of lupus; scraping and application of carbolic acid, 234—Cases of fracture of the base of the skull, 318—Two cases of extraction of cataract in which the eye first operated on successfully was lost from sympathetic ophthalmitis, following unsuccessful extraction in the second eye, 542—Scalp wound followed by brain symptoms; trephining on the thirteenth day; temporary relief; death on the twenty-fourth day after the accident; suppuration of cerebral meninges; broncho-pneumonia, 823—Compound depressed fracture of right parietal bone; trephining, with recovery for some weeks; death from cerebral abscess after healing of wound, 998
HALIFAX INFIRMARY.—Fracture of the spine; death; necropsy, 15
HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK.—Excision of a tumour from the brain, 1090
HOSPITAL FOR SICK CHILDREN.—Malformation of the external organs of generation, 773

Digitized by Google

KASHMIR MISSION HOSPITAL.—Disease of mastoid cells; operation by incision and gouging; recovery; remarks, 493
LEITH HOSPITAL.—Case of rheumatic fever with hyperpyrexia (109·2° F.) following acute tonsilitis; ice pack; temporary relief; death; necropsy, 409
LIVERPOOL INFIRMARY FOR CHILDREN.—Acute mania in a child of five years; recovery; remarks, 824
LIVERPOOL NORTHERN HOSPITAL.—Aneurysm of arch of aorta; embolism of abdominal aorta; necropsy, 368—Epithelioma of penl; complete amputation, with formation of perineal urethra; recovery, 912
LIVERPOOL ROYAL INFIRMARY.—Villous tumour of bladder; removal by median cystotomy; death, 678—Immediate gangrene of upper limb, preserved aseptic and successfully amputated at shoulder joint; recovery, 999
MANCHESTER ROYAL INFIRMARY.—Extirpation of the larynx for epithelioma; recovery, 191
MIDDLESEX HOSPITAL.—Poisoning by carbolic acid; severe bronchitis; recovery, 678
NATIVE HOSPITAL, THE, BUTTERWORTH, TRANSKEI, SOUTH AFRICA.—Case of a morphia habitué, said to have taken daily forty grains of morphia hypodermically; temporary abstention; relapse; death, 913
NORWOOD COTTAGE HOSPITAL.—Case of ovariotomy, 61—Case of ovariotomy with high adhesions; recovery, 1143
QUEEN'S HOSPITAL, BIRMINGHAM.—Primary encephaloid growth of lung; necropsy, 1047
RADCLIFFE INFIRMARY, OXFORD.—Case of sunstroke; necropsy, 542
ROYAL HOSPITAL FOR WOMEN AND CHILDREN.—Complete inversion of the uterus of nine years' duration; reduction by Aveling's repositor; cure, 590
ST. BARTHOLOMEW'S HOSPITAL.—Three cases of epithelioma of the tongue and floor of the mouth, 732—Spinal concussion, with probable fracture of the cervical spine; recovery, 1047
ST. LEONARDS HOSPITAL, SUDBURY, SUFFOLK.—Three cases of fractured patella; one treated by back splint, the others by wire suture, 774
ST. THOMAS'S HOSPITAL.—Bony ankylosis of lower jaw; removal of a wedge-shaped piece of bone on each side; recovery with good movement of jaw, 233—Two cases of disease of the thyroid gland; removal of isthmus and part of lateral lobes; cure, 367—Traumatic dislocation of hip; useless limb; excision of head of femur; successful result, 870
SAMARITAN FREE HOSPITAL.—Removal of large intra-uterine fibroid, 636
SEAMEN'S HOSPITAL, GREENWICH.—A fatal case of strangulated hernia, 952
SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Pneumonia; convalescence; gangrene of both feet; paralysis of left arm and leg, and of right side of face; Cheyne Stokes' respiration; death; necropsy; clots in right middle meningeal, right popliteal, and left anterior and posterior tibial arteries; hæmorrhagic infarct in upper lobe of left lung, 1143
SOOREE CHARITABLE DISPENSARY.—Fracture of skull; extravasation of blood on dura mater, producing compression of brain; trephining; death, 319—A case of catheter fever; death, 410—Liver abscess treated with free incision and drainage; recovery, 1092—Imperforate anus and prepuce, ib.
TAUNTON STATION HOSPITAL.—Ulcerative endocarditis; necropsy, 871
THREE COUNTIES ASYLUM, ARLESEY.—Passage of a spoon and other foreign bodies through the alimentary canal, 543
UNIVERSITY COLLEGE HOSPITAL.—Tubercular peritonitis and pleurisy; cystitis; diphtheria; necropsy, 105—Case of hydrophobia, 913
VICTORIA HOSPITAL FOR CHILDREN.—Acute yellow atrophy of liver; necropsy, 191
WEST LONDON HOSPITAL.—Rupture of the tegumentary and other coverings of an inguinal hernia through the cicatrix of an old incision for the relief of strangulation; protrusion of more than three feet of intestines; reduction; recovery, 276—Case of typhoid fever with high temperature (105·8° F.) treated by ice packing; recovery, 408—Acute traumatic (?) tetanus; death on seventh day of illness; autopsy; remarks, 492
WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Case of pachymeningitis; necropsy, 106—Buffer accident; death; necropsy revealing two ruptures of the diaphragm and protrusion of the right lobe of the liver, the spleen, and the stomach into the thoracic cavity; laceration of spleen and kidneys, 277—Strangulated inguinal hernia; death from intestinal hæmorrhage, 636—Rupture of liver; necropsy, ib.
YORK COUNTY HOSPITAL.—Six cases of excision of the knee-joint, 145

Phthisis, 669; pretubercular, a health resort in, 263; the communicability of, 311; the treatment of night sweats in, 408; disinfecting the sputa of, 502; practical remarks on, 796; in Madeira, 543; distribution of tubercle bacilli in the lesions of, 1048
Physical signs, conduction of, 917, 923
Physician, the elements of true greatness in a, 372; and patient, the relations between, 1106
Picric acid as a test for albumen and sugar in the urine, the true value of, 1083
Pike, Mr. J. B., on opening the trachea, 854
Pink fond, the, 66, 133, 441
Pin-swallowing, 622
Pippette, Mr. W., on "what is a minim?" 528
Pitts, Mr. B., on rupture of the coverings of an inguinal hernia, 346
Pityriasis maculata et circinata, 435
Placenta, peculiar form of, causing delay in the third stage of labour, 527
Plastic operation for closure of an unhealed burn, 873
Playfair, Sir L., on the waste of the profession, 213; on medical legislation, 963
Pleuritic effusion, paracentesis for, 91
Plumbing, 609
Pneumonia, iodide of potassium in, 27; lobar, 407; osseous, simulating empyema, 836; and pleuro-pneumonia, the pathology of, 135; and bronchitis, some points in the etiology of, 487; relapsing or intermittent, occurring in an aged man, 1082; relapsing, 1096; convalescence, gangrene of both feet, paralysis of left arm and leg, and of right side of face, Cheyne-Stokes' respiration, death, recovery, clots in right middle meningeal, right popliteal, and left anterior and posterior tibial arteries, hæmorrhagic infarct in upper lobe of right lung, 1143
Poisoning, cases of accidental, 189
Poland, Mr. J. H., on dislocation of the sternal end of the clavicle, backwards and upwards, 104
Police surgeons' fees, 608
Policemen, the wounded, 157
Political athlete, the, 512
Polypus, case of naso-pharyngeal, removal by the écraseur and actual cautery, after splitting the soft and cutting away the posterior third of the hard palate, 102; nasal, the treatment of, 161
Pons Varolii, case of glioma of the, 587
Pontifical hospital, the, 970
Poole, action to recover medical charges at, 607
Poor-law Medical Officers' Association, 19
Popham, Mr. J., obituary notice of, 433
Population estimates, 37
Porro's operation and laparotomy for ileus, 971
Ports, sanitary inspection of, 332
Post-mortem specimens, temporary preservation of, 79
Potassium, elimination of iodide of, 160
Powell, Mr. J., on the M.B. Pass Examination of the University of London, 1031
Power, Mr. Henry, on cocaine, 975
Pratt, Mr. J. Wyatt, on a remarkable case of umbilical tumour, 1142
Pregnancy, fœtal extensions and retroflexions during, 143; the severe, or so-called "uncontrollable," vomiting of, 918, 1098; and cancer of the breast, 207
Prepuce dilator, Richmond's, for the treatment of phimosis without operation, 544
Prepuce-grafting, 596, 676
Preputial calculi, 680
Prescot, isolation and infection at, 77
Preston Infirmary and the operatives, 1027
——— Medico-Ethical Society, 662
Prickly heat, 264, 307
Prisons, our military, 749
Pritchard, Dr. Owen, on cocaine, 1167
Proptosis with gland enlargement, 63
Prosecution, an ill-advised, 929
Prostate, a case where a scirrhous carcinoma of the, was removed, 433
Protoplasm, 500
Provident dispensaries, low remuneration of medical officers of, 1016
Pseudogliomata and purulent meningitis, 681
Public health, in the past summer, 882; Tracts (review), 495
——— parks and open spaces, 587
Puerperal fever, 280
——— septicæmia, 420; autogenetic, case of, with remarkable exacerbations and remissions, recovery, 542
Pulmonary artery, congenital contraction of orifice of, from fusion of the valves, foramen ovale open (sequel to "a case of extreme cyanosis in an adult"), 183
Pulmonary surgery, 884
Pulse, intermittent, 511
Punjab, the appointment of Surgeon-General of the, 935; mortality in the, 1122
Pure or impure? 176
Puzey, Mr. Chauncy, on prepuce grafting, 676
Pye, Mr. Walter, Surgical Handicraft, 959
Pyo-salpinx, leakage into the uterine cavity, abdominal section, drainage, recovery, 493
Pyrethrum roseum as a disinfectant, 220

"Quack" advertisements and the religious press, 759
Quarantine, the value of, 413; and the forthcoming congresses, 117; and cholera, 253; and infected ports, 253, 297, 340
Quarterly Journal of Microscopical Science (review), 783
Quebec lunatic asylums, 1059
Quebrachio, alkaloids of, 1018
Queen's College, Birmingham, introductory address at, by Dr. J. Sawyer, 640; the obstetric department of the, 1059
Quilts, ventilating, 112
Quinine and honey, 669; borate of, 559; fluoride of, ib.
Quinlan, Dr., introductory address by, at St. Vincent's Hospital, 921

Ribbeth, the late Dr., 801, 837, 847, 855; in memoriam, 908, 886; untitled heroism, 942
Rabies, canine, 47
Radcliffe, Mr. J. N., in memoriam, 502; obituary notice of, 524; Mr. Simon on, 562; the late, 651
Rags, the importation of, 119, 513, 608, 839; and cholera, 291
Railton, Dr. T. C., on mitral stenosis and insufficiency, 869
Railway carriages, overcrowding, 745
Rajputana, opium cultivation in, 306
Ranking, Dr. G. S. A., on the relation between the spleen and the thyroid, 127
Rare case, a, 855
Rat, bite of a, 290
Rawlings, Mr. B., on the National Hospital for the Paralysed and Epileptic, 1078
Reason or instinct, 1112, 1129
Recurrent myeloid epulis, excision of the lower jaw for, 1141
Rectum, stricture of the, 17; imperforate, cure, 775; supposed cancer of the, in a boy aged nineteen, 983
Red Cross Association, the, 436
Redfern, Prof., address on physiology by, 201
Redwater, 290
Reed, Dr. S. C., on small pox *alias* chicken-pox, &c., in Basutoland, 221
———, Dr. T. D., on vaccine, 435
Reeves, Mr. H. A., on colotomy and osteotomy, 39; on the treatment of ruptured kidney, 588
———, Mr. R. H., on the cholera, 531
Refuse, the right use of, 150
Regina v. C. F. J. B. Briggs and E. Briggs, 1015
Reid, Dr. R. W., on the relation of the principal fissures and convolutions of the cerebrum to the outer surface of the scalp, 539
Relapsing fever, 329
Rembrandt's pictures, engravings of, 716
Remsen, Dr. Ira, the Principles of Theoretical Chemistry with special reference to the Constitution of Chemical Compounds (review), 278
Renshaw, Mr. H., death of, 930
Renton, Dr. J. C., note on the value of hydrochlorate of cocaine in ophthalmic surgery, 992
Retention of urine in an old man, puncture of the bladder above the pubes, 1089
Retina, treatment of, recent detachment of the, 682; embolism of the, central artery of the, 1064
Retinitis albuminurica, 1096
Revaccination of school children, 193

REVIEWS AND NOTICES OF BOOKS.

Clinical Lectures on Mental Diseases: by T. S. Clouston, M.D., 17—Influence of the Mind upon the Body; second edition: by Dr. Hack Tuke, ib.—Insanity considered in its Medico-Legal Relations: by T. R. Buckham, A.M., M.D., ib.—A Text-book of Pathological Anatomy and Pathogenesis; by Ernst Ziegler; Part II.: translated and edited by Donald Macalister, M.A., M.B. 19—Manual of Pathological Histology; by Cornil and Ranvier; second edition; Vol. II., Part I.: translated by A. M. Hart, ib.—Rupture of the Urinary Bladder: by Walter Rivington, F.R.C.S., ib.—Handbook of Geographical and Historical Pathology; by Dr. August Hirsch; Vol. I., Acute Infective Diseases: translated from the second German edition by Charles Creighton, M.D., 64—The Evolution of Morbid Germs: by Kenneth W. Millican, B.A., M.R.C.S., 66—An Introduction to Pathology and Morbid Anatomy; sixth edition: by T. Henry Green, M.D., 110—The Extra Pharmacopœia of Unofficial Drugs, &c.; third edition: by W. Martindale, F.C.S., and W. Wynn Westcott, M.B. Lond., 111—A Synop-

sis of the Bacteria and Yeast Fungi: by W. B. Grove, B.A., ib.—Homburg vor der Höhe, a Health Resort: by H. S. C. W. Heyd, M.D., ib. —Wiesen as a Health Resort in Early Phthisis: by A. T. Wise, M.D., ib.—The J. E. M. Guides to Switzerland and to Davos Platz; third edition: edited by J. E. Muddoch, ib.—Our Library Table, 112, 369, 411, 495, 783, 831, 1102—Guide to the Study of Ear Disease: by P. M'Bride, M.D., 149—Manual of Diseases of the Ear: by Thomas Barr, M.D., &c., ib.—An Elementary Course of Botany by the late Professor Henfrey, F.R.S.; fourth edition: by M. T. Masters, M.D., F.R.S., and A. W. Bennett, M.A., B.Sc., ib.—The Student's Guide to Systematic Botany: by Robert Bentley, F.L.S., ib. —Aids to Botany; second edition: by Armand Semple, ib.—The Elements of Physiological and Pathological Chemistry: by T. Crawstoun Charles, M.D., 236—A Statistical Inquiry into the Nature and Treatment of Epilepsy: by A. Hughes Bennett, M.D., ib.—Medical Electricity: by A. de Watteville, M.A., M.D., 237—Practical Manual of Diseases of Women and Uterine Therapeutics for Students and Practitioners: by H. Macnaughton Jones, M.D., 277 —Poisons; their Effects and Detection: by Alexander Wynter Blyth, M.R.C.S., F.C.S., ib. —A Treatise on Chemistry; Vol. III., Part II.: by H. E. Roscoe, F.R.S., and C. Schorlemmer, F.R.S., 278—The Principles of Theoretical Chemistry: by Ira Remsen, M.D., Ph.D., ib.—A Short Text-book of Inorganic Chemistry, by Dr. Herman Kolbe: translated by T. S. Humpidge, Ph.D., ib.—A Text-book of Inorganic Chemistry; by Prof. Victor von Richter: translated by Edgar F. Smith, A.M., ib.—The London Water-supply—Past, Present, and Future: by G. Phillips Bevan, F.S.S., ib.—Some International Health Literature, 279—Die Tuberculose der Knochen und Gelenke: bearbeitet von Fr. Kœnig, 321—Specificity and Evolution in Disease: by W. J. Collins, M.D., ib —Sleep-Walking and Hypnotism: by D. Hack Tuke, M.D., ib.—Western African Hygiene: by Charles Scovell Grant, M.D., ib.—A Medical Guide to the Principal Health Resorts of Northern England: by Richard Ellis, 322—Health Studies: by H. Sinclair Paterson, M.D., ib.—La Santé du Peuple: par L. Evrard, ib.—The Laws of Health, Physiology, Hygiene, Stimulants, Narcotics: by J. C. Hutchison, M.D., ib. —Compendium der Pathologisch Anatomischen Diagnostik; third edition: von. Dr. Johannes Orth, 369—Post-Nasal Catarrh: by Edward Woakes, M.D.Lond., ib.—The Non-Bacillar Nature of Abrus Poison: by C. J. H. Warden and L. A. Waddell, 410—Thirty Years' Experience of a Medical Officer in the English Convict Service: by John Campbell, M.D, Staff Surgeon R.N., 411—Report on the Scientific Results of the voyage of H.M.S. *Challenger* during the years 1873 to 1876, under the command of Captains Nares and Thomson Zoology, Vol. VII.: prepared under the superintendence of the late Sir C. Wyville Thomson, Knt., F.R.S., and now of John Murray, F.R.S.E., one of the Naturalists of the Expedition, 494—Principes Techniques d'Assainissement des Villes et Habitations: by A. Wazeu, Civil Engineer, ib.—A Practical Treatise on Materia Medica and Therapeutics; fifth edition: by Roberts Bartholow, M.A., M.D., LL.D., &c., 495 —The Science and Art of Surgery, &c: by John Eric Erichsen, F.R.S., LL.D., F.R.C.S.; eighth edition: revised and edited by Marcus Beck, M.B. and M.B. Lond., F.R.C.S., 593—A Manual for the Practice of Surgery; fourth edition: by Thomas Bryant, F.R.C.S., ib.—Lectures on Diseases of Infancy and Childhood; seventh edition: by Charles West, M.D., 633—Injuries and Diseases of the Jaw (Jacksonian Prize Essay, 1867); third edition: by Christopher Heath, F.R.C.S., 683—Manual of the Dissection of the Human Body; fifth edition; by Luther Holden: edited by John Langton, ib.—Diseases of the Heart and Thoracic Aorta: by Byrom Bramwell, M.D., F.R.C.P.E., 782—Intestinal Obstruction, with an Appendix on the Action of Remedies: by Hugh Owen Thomas, M.R.C.S., 830—Abdominal Hernia: by Rushton Parker, B.S., F.R.C.S., ib. — Lectures on some important Points connected with the Surgery of the Urinary Organs; students' edition: by Sir H. Thompson, F.R.C.S., M.B. Lond., 874—On Tumours of the Bladder; their Nature, Symptoms, and Surgical Treatment: by the same Author, ib.—A Handbook of Ophthalmic Science and Practice: by Henry E. Juler, F.R.C.S., ib.—Dental Medicine; a Manual of Dental Materia Medica and Therapeutics for Practitioners and Students: by Ferdinand J. S. Gorgas, A.M., M.D., D.D.S., 975—Brain; a Journal of Neurology, Part XXVII., October, 1884, ib.—On Sclerosis of the spinal Cord: by Julius Althaus, M.D., M.R.C.P., 920—Transactions of the Academy of Medicine in Ireland, Vol. II., ib.—The National Dispensatory, third edition: by Alfred Stillé, M.D., LL.D., and John M. Maisch, Phar.D., ib.—Life in the Soudan: by Dr. Josiah Williams, F.R.G.S., ib.—The Asclepiad: by Dr. B. W. Richardson, ib.—Elements of Surgical Diagnosis: by A. Pearce Gould, M.S., M.B. Lond., F.R.C.S. Eng., 968—The Elements of Physiological Physics: by J. M'Gregor-Robertson, M.A., M.B., C.M., ib.—Materia Medica and Therapeutics; an Introduction to the Rational Treatment of Disease: by J. Mitchell Bruce, M.A., M.D., F.R.C.P., ib.—Surgical Handicraft; a Manual of Surgical Manipulations, &c.: by Walter Pye, F.R.C.S., 959—A Handbook of the Diseases of the Eye and their Treatment: by Henry R. Swanzy, A.M., M.B, 1005—Humphry Sandwith; a Memoir: compiled from Autobiographical Notes by his Nephew, T. Humphry Ward, 1006—A Practical Treatise on the Medical and Surgical Uses of Electricity; fourth edition: by Geo. M. Beard, M.D., and A. D. Rockwell, M.D., 1051—A Manual of Diseases of the Throat and Nose, Vol. II.: by Morell Mackenzie, M.D., 1052—Diseases of the Spinal Cord; second edition: by Byrom Bramwell, M.D., ib.—Fat and Blood; third edition: by S. Weir Mitchell, M.D., ib.—Elements of Modern Chemistry; by Adolphe Wurtz: translated by W. H. Greene, M.D., ib. —The Journal of Anatomy and Physiology, Vol. XVIII. Part IV., ib.—Notes on Materia Medica and Pharmacy; by Frederick T. Roberts, M.D., ib.—Transactions of the Clinical Society, Vol. XVII., 1053—Orthopædic Apparatus: by F. Gustav Ernst, ib.—La Gymnastique: by A. Collineau, M.D., 1101—Pyuria, or Pus in the Urine, and its Treatment; by Dr. Robert Ultzmann: translated by Dr. W. B. Platt, 1148—Aids to Public Health; by Dr. J. L. W. Thudichum, ib.—Diabetes Mellitus: by Harvey J. Philpot, 1149—Evolution in History, Language, and Science, ib.—Hints for Invalids and Travellers, with Observations on the Climate of Luxor and Egypt during Three Years' Residence, 1877-78-79: by T. E. Maclean, M.S., ib.—The most Delightful Voyage in the World, England to the Cape of Good Hope, and South Africa as a Health Resort: by A. Wilmot, ib.—Recent Materia Medica: by F. Harwood Lescher, F.C.S., ib.—Leaders in Modern Philanthropy: by W. Garden Blaikie, D.D., ib.—Diaries, Calendars, &c., ib.—Magazines, &c., ib.

Reynolds, Dr. J., Experimental Chemistry for Junior Students (review), 411
———, Dr. J. Russell, Harveian Oration by, 717
———, Mr. H. S., on a case of autogenetic puerperal septicæmia, with remarkable exacerbations and remissions, recovery, 543
Rheumatic affections, nerve symptoms in, 679
——— arteritis (?) acute, 964
——— fever, case of, with hyperpyrexia (109·2°F.) following acute tonsilitis, ice pack, temporary relief, death, necropsy, remarks, 499
Rhinitis, chronic hypertrophic, 779
Richardson, Dr. B. W., the Guild of Good Life (review), 412
———, Dr., of Rhayader, death of, 348
Richmond, Mr. W. S., prepuce dilator of, 544
Richter, Professor V. von, a Text-book of Inorganic Chemistry (review), 278
Rideal, Mr. C. F., on vaccination with old lymph, 220
Riding v. driving, 714, 761
Ringer, Dr. S., and Dr. Harrington Sainsbury, on the nervous or muscular origin of certain spastic conditions of the voluntary muscles, 767, 815, 860
Rivington, Mr. W., Rupture of the Urinary Bladder (review), 18, 90
Roberts, Dr. F. T., Notes on Materia Medica and Pharmacy (review), 1052
Robertson, Mr. J. C., on a method of treating sprains, 351
Robson, Mr. A. W. Mayo, on the College of Surgeons Examinations, 801; on irritation of the skin following the application of vaseline as a surgical dressing, 822
Roche, Dr. J., on cholera, 126
Rogers, Dr. J., on the Poor-law Medical Officers' Association, 19
———, Mr. T. K., death of, 291, 380
Roman Campagna, amelioration of the, 971
Rome, the water-supply of, 933, 1125
Roocroft, Mr. W. Mitchell, on the radical cure of umbilical hernia, 187
Roscoe, Sir H., 79; and Mr. C. Schorlemmer, a Treatise on Chemistry (review), 278
Royal Albert Hospital, 1027
——— College of Physicians, 129, *passim*; and cholera, 244; Harveian Oration, 717; combination with the Royal College of Surgeons, 790; the new conjoint scheme of the, 876, 972
——— College of Surgeons, England, the, 87, *passim*; election of Council of the, 20, 23, 72; presidency of, 67, 115; museum, 74; resolutions of the council of, 113; calendar of the, 598; Association of Fellows of, 700, 757, 795, 887; combination with the Royal College of Physicians, 790; examinations, 801; the new conjoint scheme, 876, 972; reform at, 876, 924, 1110, 1124; Association of Members of, 933; library of, 899, 941, 994; the court of examiners and the council of, 1011; examiners under the combined scheme, 1012; —of Ireland, Medical School, introductory address by Mr. Stack, 921
Royal doctors, 1013
——— Hospital for Incurables, the, 1075
——— Medical and Chirurgical Society, 1058
——— Medical Benevolent College, 669
——— Microscopical Society, 1027
——— Society, 1027; medals, 939
——— Society for the Prevention of Cruelty to Animals, 83
Rugby, the Hospital of St. Cross, 130
"Rule of life," laying down a, 788

Sacral tumour, congenital, a correction for the "System of Surgery," 620
St. Albans, enteric fever and milk infection at, 931
St. George's Hospital, 813; introductory address at, by Dr. Champneys, 625
St. George's-in-the-East, insanitary houses in, 1118
St. John Ambulance Association, 219, 620, 895
——— of Jerusalem, the order of (English language), 851
St. Mary's Hospital, the new wing of, 34; introductory address by Dr. Lees, 696
St. Thomas's Hospital, Royal visit to, 216; paying patients at, 378; non-paying patients at, 509; inaugural address at, 579; Medical College, 66
St. Vincent's Hospital, introductory address at, 921
Salford Union Hospital, fire at, 768
Salop and North Wales Eye, Ear, and Throat Hospital, 219
Salt tax, the, and cholera, 205, 290
Sanitary administration, metropolitan, 780
——— Assurance Association, the, 174, 666, 1018, 1067
——— co-operation, 1012
——— houses, 174
——— Institute of Great Britain, 43, 131, 674
Sanitation in the bedroom, 1171
Sardines, a case of poisoning by, 540
Saundby, Dr. R., on chorea in the aged, 948
Savory, Mr. W. S., on the pathology of cancer, 1033
Sawyer, Dr. J., introductory address by, at Queen's College, Birmingham, 640
Scalp wound, followed by brain symptoms, trephining, temporary relief, death, 833
Scapula, ununited fracture of the spine of the, 782
Scarlatina latens, 715
Scarlatinal uræmia, 46
Scarlet fever, convalescents from, 119; the importance of isolating slight and doubtful cases of, 400; the etiology of, 604; surgical, 872, 881
Schaeffer, Dr. E. M., on earth as a dressing for sprains, 668
Scholarships, 658, 781
School children, penny dinners for, 421
Schools, over-pressure in, 283, 547, 570, 616, 652, 662, 698, 879, 977, 1016, 1113; at the Health Exhibition, 203; hygiene and, 158, 242; School Board for London, the, and, 788; management of epidemics of infectious diseases in, 194; ventilation of, 622, 1030; elementary, food and study in, 1108
Sciatica, cure for, 423
Sclerosis, disseminated, eye symptoms in, 335
Scopolia japonica, 556
Scoresby-Jackson, Dr. T., appeal to public vaccinators, 623, 759
Scotch medical education and examinations, 1099, 1171
Scotland, lunacy in, 610
Scrofula and tubercle, 995
Sea-bathing, the origin of, 375
Seaman, Dr. W. C., on cholera, its etiology and treatment, 126
Seamen's Hospital, Greenwich, 130
Semon, Dr. F., on cocaine as a local anæsthetic in intra-laryngeal operations, 912; on an electric laryngoscope, a warning, 1124
Semple, Dr. S. H., on the Weldon case, 215
———, Mr. A., Aids to Botany (review), 149
Sentiment, inherited, 264
Septicæmia, intestinal, 244
Session, opening of the winter, 601
Sewage, the value of, 808
Sewer ventilating pipes opening at high levels, 556
Sewill, Mr. H., on the prevention of dental caries, 402; on stopping teeth at general hospitals, 754
Sewing-machine work, 394
Sexton, Dr. S., on the treatment of a case of acute catarrhal inflammation of the middle ear

Digitized by Google

by removal of accumulated secretions from the tympanum through the Eustachian tube, 677
Shapley, Mr. F., on tobacco, 896
Shearer, Dr. G., Opium Smoking and Opium Eating (review), 412
——, Mr. T. L., on a new method of treating sprains, 233
Sheffield, the recent epidemic of small-pox in, 830; General Infirmary, 323
Shelley, Mr. C. E., a correction by, 235
Shepherd, Mr. R. J., on a successful operation for hernia in a patient with Bright's disease, 1125
Shetland, cruel quarantine in, 76
Ship surgeons, 331, 761
Shoemaker, Dr. J. V., on jequirity (abrus precatorius, Linné), its use in diseases of the skin, 185; the oleates of, 377; on the treatment of syphilis by hypodermic injections of corrosive sublimate, 406
Shop emancipation, 327
Shoreditch, sanitation in, 723
Shoulder, curious cause of dislocation of the, 440
Shrewsbury, the drainage of, 176
Shroff, Mr. D. S., on total suppression of urine for nine days, recovery, 1090
Shuckburgh, Lady, the accident to, 247
Siamese theory and practice of medicine, 985
Sick and injured, removal of the, 164; principles which underlie the construction of appliances for the removal of, 96
Simla and Murree, typhoid fever at, 557
Simmons, Dr. G. H., on medical education in America, 1032
Simon, Mr., on John Netten Radcliffe, 562
Simpson, Mr. Spencer B., on the dangers of wearing hair-pins, 668
Sinclair, Mr. J., on vaccination v. small-pox, 306
Singh, some statistics and observations regarding lithotomy in the Hyderabad Civil Hospital, 312
"Sister Grace," 28, 90
Sizer, Dr. N. B. de S., on poisoning by ice cream, 441; "what is a minim?" 621; on the water-supply of Rome, 986
Sizygium, 208
Skin, remarkable colouration of the, 1131
Skull, cases of fracture of the base of the, 318; extensive extravasation of blood on dura mater, producing compression of brain, trephining, partial relief of symptoms, death, 319; followed by encephalitis, ataxia, and aphasia, recovery, 910
Skulls, Chinese, 593
Slaughtering, painless, 71
Sling, a pin, 541
Small-pox, the diffusion of, 78, 896; diagnosis of 85; in South Africa, 115, 158, 221, 420; in Newcastle, 118; at Windsor and Aldershot, 120; the death rate from, in Chester in 1774, 193; at the Diamond Fields, 203, 246, 748; hospitals, the influence of, 228, 933; in the army and navy, 526; and enteric fever in the North, 749; in Victoria, 750; and blindness, 705, 843; epidemic, the cost of a, 835, 943; atmospheric dissemination of, 929; wilful exposure of, 1017; in London and other large English towns, 1058; patients, the removal of, 1108; in London, 1115; at Trieste, 1115; at Sheffield, 1162
